

Modelica[®] - A Unified Object-Oriented Language for Physical Systems Modeling

Language Specification

Version 2.0

July 10, 2002

by the

Modelica Association

Abstract

This document defines the Modelica language, version 2.0, which is developed by the Modelica Association, a non-profit organization with seat in Linköping, Sweden. Modelica is a freely available, object-oriented language for modeling of large, complex, and heterogeneous physical systems. It is suited for multi-domain modeling, for example, mechatronic models in robotics, automotive and aerospace applications involving mechanical, electrical, hydraulic and control subsystems, process oriented applications and generation and distribution of electric power. Models in Modelica are mathematically described by differential, algebraic and discrete equations. No particular variable needs to be solved for manually. A Modelica tool will have enough information to decide that automatically. Modelica is designed such that available, specialized algorithms can be utilized to enable efficient handling of large models having more than one hundred thousand equations. Modelica is suited and used for hardware-in-the-loop simulations and for embedded control systems. More information is available at <http://www.Modelica.org/>

1 Introduction

1.1 Overview of Modelica

Modelica is a language for modeling of physical systems, designed to support effective library development and model exchange. It is a modern language built on non-causal modeling with mathematical equations and object-oriented constructs to facilitate reuse of modeling knowledge.

1.2 Scope of the specification

The semantics of the Modelica language is specified by means of a set of rules for translating a model described in the Modelica language to the corresponding model described as a flat hybrid DAE. The key issues of the translation (or instantiation in object-oriented terminology) are:

- Expansion of inherited base classes
- Parameterization of base classes, local classes and components
- Generation of connection equations from **connect** statements

The flat hybrid DAE form consists of:

- Declarations of variables with the appropriate basic types, prefixes and attributes, such as "parameter Real v=5".
- Equations from equation sections.
- Function invocations where an invocation is treated as a set of equations which involves all input and all result variables (number of equations = number of basic result variables).
- Algorithm sections where every section is treated as a set of equations which involves the variables occurring in the algorithm section (number of equations = number of different assigned variables).
- When clauses where every when clause is treated as a set of conditionally evaluated equations, also called instantaneous equations, which are functions of the variables occurring in the clause (number of equations = number of different assigned variables).

Therefore, a flat hybrid DAE is seen as a set of equations where some of the equations are only conditionally evaluated (e.g. instantaneous equations are only evaluated when the corresponding when-condition becomes true).

The Modelica specification does not define the result of simulating a model or what constitutes a mathematically well-defined model.

1.3 Definitions and glossary

The semantic specification should be read together with the Modelica grammar. Non-normative text, i.e., examples and comments, are enclosed in *[]*, comments are set in *italics*.

Term	Definition
Component	An element defined by the production component-clause in the Modelica grammar.
Element	Class definitions, extends-clauses and component-clauses declared in a class.
Instantiation	The translation of a model described in Modelica to the corresponding model described as a hybrid DAE, involving expansion of inherited base classes, parameterization of base classes, local classes and components, and generation of connection equations from connect statements.

2 Modelica syntax

2.1 Lexical conventions

The following syntactic meta symbols are used (extended BNF):

```
[ ] optional
{ } repeat zero or more times
```

The following lexical units are defined:

```
IDENT = NONDIGIT { DIGIT | NONDIGIT }
NONDIGIT = "_" | letters "a" to "z" | letters "A" to "Z"
STRING = "" { S-CHAR | S-ESCAPE } ""
S-CHAR = any member of the source character set except double-quote "", and backslash "\"
S-ESCAPE = "\" | "\" | "\"?\" | "\" |
           "\"a\" | "\"b\" | "\"f\" | "\"n\" | "\"r\" | "\"t\" | "\"v\"
DIGIT = "0" | "1" | "2" | "3" | "4" | "5" | "6" | "7" | "8" | "9"
UNSIGNED_INTEGER = DIGIT { DIGIT }
UNSIGNED_NUMBER = UNSIGNED_INTEGER [ "." [ UNSIGNED_INTEGER ] ]
                  [ ( "e" | "E" ) [ "+" | "-" ] UNSIGNED_INTEGER ]
```

Note: string constant concatenation "a" "b" becoming "ab" (as in C) is replaced by the "+" operator in Modelica.

Modelica uses the same comment syntax as C++ and Java, and also has structured comments in the form of annotations and string comments. Inside a comment, the sequence <HTML> </HTML> indicates HTML code which may be used by tools to facilitate model documentation.

Bold face denotes keywords of the Modelica language. Keywords are reserved words and may not be used as identifiers, with the exception of `initial` which is a keyword in section headings, but it is also possible to call the function `initial()`.

2.2 Grammar

2.2.1 Stored definition

```
stored_definition:
  [ within [ name ] ";" ]
  { [ final ] class_definition ";" }
```

2.2.2 Class definition

```
class_definition :
  [ encapsulated ]
  [ partial ]
  ( class | model | record | block | connector | type |
    package | function )
  IDENT class_specifier
```

```

class_specifier :
  string_comment composition end IDENT
  | "=" base_prefix name [ array_subscripts ] [ class_modification ]
comment
  | "=" enumeration "(" [enum_list] ")" comment

base_prefix :
  type_prefix

enum_list    : enumeration_literal { "," enumeration_literal}

enumeration_literal : IDENT comment

composition  :
  element_list
  { public element_list |
    protected element_list |
    equation_clause |
    algorithm_clause
  }
  [ external [ language_specification ]
    [ external_function_call ] ";" [ annotation ";" ] ]

language_specification :
  STRING

external_function_call :
  [ component_reference "=" ]
  IDENT "(" [ expression { "," expression } ] ")"

element_list :
  { element ";" | annotation ";" }

element :
  import_clause |
  extends_clause |
  [ final ]
  [ inner | outer ]
  ( ( class_definition | component_clause ) |
    replaceable ( class_definition | component_clause )
    [constraining_clause comment])

import_clause :
  import ( IDENT "=" name | name [ "." "*" ] ) comment

```

2.2.3 Extends

```

extends_clause :
  extends name [ class_modification ]

```

```
constraining_clause :
  extends_clause
```

2.2.4 Component clause

```
component_clause:
  type_prefix type_specifier [ array_subscripts ] component_list
```

```
type_prefix :
  [ flow ]
  [ discrete | parameter | constant ] [ input | output ]
```

```
type_specifier :
  name
```

```
component_list :
  component_declaration { "," component_declaration }
```

```
component_declaration :
  declaration comment
```

```
declaration :
  IDENT [ array_subscripts ] [ modification ]
```

2.2.5 Modification

```
modification :
  class_modification [ "=" expression ]
  | "=" expression
  | "!=" expression
```

```
class_modification :
  "(" [ argument_list ] ")"
```

```
argument_list :
  argument { "," argument }
```

```
argument :
  element_modification
  | element_redeclaration
```

```
element_modification :
  [ each ] [ final ] component_reference modification string_comment
```

```
element_redeclaration :
  redeclare [ each ] [ final ]
  ( ( class_definition | component_clause1 ) |
    replaceable ( class_definition | component_clause1 )
    [constraining_clause])
```

```
component_clause1 :
  type_prefix type_specifier component_declaration
```

2.2.6 Equations

```

equation_clause :
  [ initial ] equation { equation ";" | annotation ";" }

algorithm_clause :
  [ initial ] algorithm { algorithm ";" | annotation ";" }

equation :
  ( simple_expression "=" expression
  | conditional_equation_e
  | for_clause_e
  | connect_clause
  | when_clause_e
  | IDENT function_call )
  comment

algorithm :
  ( component_reference ( ":" expression | function_call )
  | "(" expression_list ")" ":" component_reference function_call
  | conditional_equation_a
  | for_clause_a
  | while_clause
  | when_clause_a )
  comment

conditional_equation_e :

  ]
  end if

conditional_equation_a :
  if expression then
    { algorithm ";" }
  { elseif expression then
    { algorithm ";" }
  }
  [ else
    { algorithm ";" }
  ]
  end if

for_clause_e :
  for for_indices loop
    { equation ";" }

```

```

end for

for_clause_a :
  for for_indices loop
    { algorithm ";" }
  end for

for_indices :
  for_index {"," for_index}

for_index:
  IDENT [ in expression ]

while_clause :
  while expression loop
    { algorithm ";" }
  end while

when_clause_e :
  when expression then
    { equation ";" }
  { elseif expression then
    { equation ";" } }
  end when

when_clause_a :
  when expression then
    { algorithm ";" }
  { elseif expression then
    { algorithm ";" } }
  end when

connect_clause :
  connect "(" connector_ref "," connector_ref ")"

connector_ref :
  IDENT [ array_subscripts ] [ "." IDENT [ array_subscripts ] ]

```

2.2.7 Expressions

```

expression :
  simple_expression
  | if expression then expression { elseif expression then expression } else
  expression

simple_expression :
  logical_expression [ ":" logical_expression [ ":" logical_expression ] ]

logical_expression :

```

```

    logical_term { or logical_term }

logical_term :
    logical_factor { and logical_factor }

logical_factor :
    [ not ] relation

relation :
    arithmetic_expression [ rel_op arithmetic_expression ]

comment :  
  string_comment [ annotation ]  
  
string_comment :  
  [ STRING { "+" STRING } ]  
  
annotation :  
  annotation class_modification
```

3 Modelica semantics

3.1 Fundamentals

Instantiation is made in a context which consists of an environment and an ordered set of parents.

3.1.1 Scoping and name lookup

3.1.1.1 Parents

The classes lexically enclosing an element form an ordered set of parents. A class defined inside another class definition (the parent) precedes its enclosing class definition in this set.

Enclosing all class definitions is an unnamed parent that contains all top-level class definitions, and not-yet read classes defined externally as described in section 3.1.4. The order of top-level class definitions in the unnamed parent is undefined.

During instantiation, the parent of an element being instantiated is a partially instantiated class. *[For example, this means that a declaration can refer to a name inherited through an extends clause.]*

[Example:

```

class C1 ... end C1;
class C2 ... end C2;
class C3
  Real x=3;
  C1 y;
  class C4
    Real z;
  end C4;
end C3;

```

The unnamed parent of class definition C3 contains C1, C2, and C3 in arbitrary order. When instantiating class definition C3, the set of parents of the declaration of x is the partially instantiated class C3 followed by the unnamed parent with C1, C2, and C3. The set of parents of z is C4, C3 and the unnamed parent in that order.]

3.1.1.2 Static name lookup

Names are looked up at class instantiation to find names of base classes, component types, etc. Implicitly defined names of record constructor functions are ignored during type name lookup *[since a record and the implicitly created record constructor function, see section 3.4.8.3, have the same name]*. Names of record classes are ignored during function name lookup.

For a simple name *[not composed using dot-notation]* lookup is performed as follows:

- First look for implicitly declared iteration variables if inside the body of a for-loop, section 3.3.3, or if inside the body of a reduction expression, section 3.4.3.1.

- When an element, equation or algorithm is instantiated, any name is looked up sequentially in each member of the ordered set of parents until a match is found or a parent is encapsulated. In the latter case the lookup stops except for the predefined types, functions and operators defined in this specification.
- This lookup in each scope is performed as follows
 1. Among declared named elements (class_definition and component_declaration) of the class (including elements inherited from base-classes).
 2. Among the import names of qualified import statements in the lexical scope. The import name of `import A.B.C;` is C and the import name of `import D=A.B.C;` is D.
 3. Among the public members of packages imported via unqualified import-statements in the lexical scope. It is an error if this step produces matches from several unqualified imports.

[Note, that import statements defined in inherited classes are ignored for the lookup, i.e. import statements are not inherited.]

For a composite name of the form A.B *[or A.B.C, etc.]* lookup is performed as follows:

- The first identifier *[A]* is looked up as defined above.
- If the first identifier denotes a component, the rest of the name *[e.g., B or B.C]* is looked up among the declared named component elements of the component.
- If the identifier denotes a class, that class is temporarily instantiated with an empty environment (i.e. no modifiers, see section 3.1.2) and using the parents of the denoted class. The rest of the name *[e.g., B or B.C]* is looked up among the declared named elements of the temporary instantiated class. If the class does not satisfy the requirements for a package, the lookup is restricted to encapsulated elements only.

[The temporary class instantiation performed for composite names follow the same rules as class instantiation of the base class in an extends clause, local classes and the type in a component clause, except that the environment is empty.]

Lookup of the name of an imported package or class, e.g. A.B.C in the statements **import** A.B.C; **import** D=A.B.C; **import** A.B.C.*, deviates from the normal lexical lookup by starting the lexical lookup of the first part of the name at the top-level.

Qualified import statements may only refer to packages or elements of packages, i.e. in "import A.B.C;" or "import D=A.B.C" A.B must be a package. Unqualified import statements may only import from packages, i.e. in "import A.B.*;" A.B must be a package. [Note, "import A;" A can be any class as element of the unnamed top-level package]

3.1.1.3 Dynamic name lookup

An element declared with the prefix **outer** *references* an element instance with the same name but using the prefix **inner** which is nearest in the enclosing *instance* hierarchy of the **outer** element declaration.

There shall exist at least one corresponding **inner** element declaration for an **outer** element reference. *[Inner/outer components may be used to model simple fields, where some physical quantities, such as gravity vector, environment temperature or environment pressure, are accessible from all components in a specific model hierarchy. Inner components are accessible throughout the model, if they are not "shadowed" by a corresponding non-inner declaration in a nested level of the model hierarchy.]*

[Simple Example:

```

class A
  outer Real T0;
  ...
end A;

class B
  inner Real T0;
  A a1, a2;    // B.T0, B.a1.T0 and B.a2.T0 is the same variable
  ...
end B;

```

More complicated example:

```

class A
  outer Real TI;
  class B
    Real TI;
    class C
      Real TI;
      class D
        outer Real TI; //
        end D;
        D d;
      end C;
      C c;
    end B;
    B b;
  end A;

class E
  inner Real TI;
  class F
    inner Real TI;
    class G
      Real TI;
      class H
        A a;
        end H;
        H h;
      end G;
      G g;
    end F;
    F f;
  end E;

class I
  inner Real TI;
  E e;
  // e.f.g.h.a.TI, e.f.g.h.a.b.c.d.TI, and e.f.TI is the same variable
  // But e.f.TI, e.TI and TI are different variables

```

```

    A a; // a.TI, a.b.c.d.TI, and TI is the same variable
  end I;
]

```

Outer element declarations shall not have modifications. The inner component shall be a subtype of the corresponding outer component. *[If the two types are not identical, the type of the **inner** component defines the instance and the **outer** component references just part of the **inner** component].*

[Example:

```

class A
  outer parameter Real p=2; // error, since modification
end A;

class A
  inner Real TI;
  class B
    outer Integer TI; // error, since A.TI is no subtype of A.B.TI
  end B;
end A;

```

Inner declarations can be used to define field functions, such as position dependent gravity fields, e.g.:

```

function A
  input Real u;
  output Real y;
end A;

function B // B is a subtype of A
  extends A;
algorithm
  ...
end B;

class C
  inner function fc = B; // define function to be actually used
  class D
    outer function fc = A;
    ...
  equation
    y = fc(u); // function B is used.
  end D;
end C;
]

```

3.1.2 Environment and modification

3.1.2.1 Environment

The environment contains arguments which modify elements of the class (e.g., parameter changes). The environment is built by merging class modifications, where outer modifications override inner modifications.

3.1.2.2 Merging of modifications

Merging of modifiers means that outer modifiers override inner modifiers. The merging is hierarchical, and a value for an entire non-simple overrides value modifiers for all components., and it is an error if this overrides a final attribute for a component. When merging modifiers each modification keeps its own **each**-attribute.

[The following larger example demonstrates several aspects:

```

class C1
  class C11
    parameter Real x;
  end C11;
end C1;
class C2
  class C21
    ...
  end C21;
end C2;
class C3
  extends C1;
  C11 t(x=3);           // ok, C11 has been inherited from C1
  C21 u;                // ok, even though C21 is inherited below
  extends C2;
end C3;

```

The environment of the declaration of *t* is (*x=3*). The environment is built by merging class modifications, as shown by:

```

class C1
  parameter Real a;
end C1;
class C2
  parameter Real b,c;
end C2;
class C3
  parameter Real x1;           // No default value
  parameter Real x2 = 2;      // Default value 2
  parameter C1 x3;            // No default value for x3.a
  parameter C2 x4(b=4);       // x4.b has default value 4
  parameter C1 x5(a=5);       // x5.a has default value 5
  extends C1;                  // No default value for inherited element a
  extends C2(b=6,c=77);       // Inherited b has default value 6
end C3;
class C4
  extends C3(x2=22, x3(a=33), x4(c=44), x5=x3, a=55, b=66);
end C4;

```

Outer modifications override inner modifications, e.g., *b=66* overrides the nested class modification of *extends C2 (b=6)*. This is known as *merging of modifications*: *merge ((b=66) , (b=6)) becomes (b=66)*.

An instantiation of class *C4* will give an object with the following variables:

Variable	Default value
----------	---------------

<i>x1</i>	<i>none</i>
<i>x2</i>	22
<i>x3.a</i>	33
<i>x4.b</i>	4
<i>x4.c</i>	44
<i>x5.a</i>	<i>x3.a</i>
<i>a</i>	55
<i>b</i>	66
<i>c</i>	77

J

3.1.2.3 Single modification

Two arguments of a modification shall not designate the same primitive attribute of an element. When using qualified names the different qualified names starting with the same identifier are merged into one modifier.

[Example:

```

class C1
  Real x[3];
end C1;
class C2 = C1(x=ones(3), x[2]=2); // Error: x[2] designated twice
class C3
  class C4
    Real x;
  end C4;
  C4 a(x.unit = "V", x.displayUnit="mV", x=5.0);
  // Ok, different attributes designated (unit, displayUnit and value)
  // identical to:
  C4 b(x(unit = "V", displayUnit="mV") = 5.0));
end C3;

```

J

3.1.2.4 Instantiation order

The name of a declared element shall not have the same name as any other element in its partially instantiated parent class. A component shall not have the same name as its type specifier.

Variables and classes can be used before they are declared.

[In fact, declaration order is only significant for:

- *Functions with more than one input variable called with positional arguments, section 3.4.8.*
- *Functions with more than one output variable, section 3.4.8.*
- *Records that are used as arguments to external functions, section 6.2.3*
- *Enumeration literal order within enumeration types, section 3.2.7.1.*

]

In order to guarantee that elements can be used before they are declared and that elements do not depend on the order of their declaration in the parent class, the instantiation proceeds in the following steps:

Flattening

First the names of declared local classes and components are found. Here modifiers are merged to the local elements and redeclarations take effect. Then base-classes are looked up, flattened and inserted into the class. The lookup of the base-classes should be independent *[The lookup of the names of extended classes should give the same result before and after flattening the extends clauses. One should not find any element used during this flattening by lookup through the extends clauses. It should be possible to flatten all extends clauses in a class before inserting the result of flattening. Local classes used for extends should be possible to flatten before inserting the result of flattening the extends clauses.]*

Instantiation

Flatten the class, apply the modifiers and instantiate all local elements.

Check of flattening

Check that duplicate elements *[due to multiple inheritance]* are identical after instantiation.

Modifiers for array elements

The each keyword on a modifier requires that it is applied in an array declaration/modification, and the modifier is applied individually to each element of the array. If the modified element is a vector and the modifier does not contain the each-attribute, the modification is split such that the first element in the vector is applied to the first element of the vector of elements, the second to the second element, etc. Matrices and general arrays of elements are treated by viewing those as a vectors of vectors etc.

If the modified element is a vector with subscripts the subscripts must be Integer literals.

If a nested modifier is split, the split is propagated to all elements of the nested modifier, and if they are modified by the each-keyword the split is inhibited for those elements. If the nested modifier that is split in this way contains re-declarations that are split it is illegal.

[Example:

```

model C
  parameter Real a [3];
  parameter Real d;
end C;
model B
  C c[5] (each a = {1,2,3}, d={1,2,3,4,5});
end B;

```

This implies that $c[i].a[j]=j$, and $c[i].d=i$.]

Subtyping and type equivalence

3.1.3.1 Subtyping of classes

For any classes S and C, S is a supertype of C and C is a subtype of S if they are equivalent or if:

- every public declaration element of S also exists in C (according to their names)

- those element types in S are supertypes of the corresponding element types in C.

A base class is the class referred to in an extends clause. The class containing the extends clause is called the derived class. *[Base classes of C are typically supertypes of C, but other classes not related by inheritance can also be supertypes of C.]*

3.1.3.2 Subtyping of components

Component B is subtype of A if:

- Both scalars or arrays with the same number of dimensions
- The type of B is subtype of the base type of A (base type for arrays)
- For every dimension of an array
 - The size of A is indefinite, or
 - The value of expression (size of B) - (size of A) is constant equal to 0 (in the environment of B)

3.1.3.3 Type equivalence

Two types T and U are equivalent if:

- T and U denote the same built-in type (one of RealType, IntegerType, StringType or BooleanType), or
- T and U are classes, T and U contain the same public declaration elements (according to their names), and the elements types in T are equivalent to the corresponding element types in U.

3.1.3.4 Type identity

Two elements T and U are identical if:

- T and U are equivalent,
- they are either both declared as **final** or none is declared **final**,
- for a component their type prefixes (see section 3.2.1) are identical, and
- if T and U are classes, T and U contain the same public declaration elements (according to their names), and the elements in T are identical to the corresponding element in U.

3.1.3.5 Ordered type identity

Two elements T and U are ordered type identical if and only if:

- T and U are type identical
- If T and U are classes
 - T and U have the same number of elements
 - The i:th declaration element of T and the i:th declaration element of U are ordered type identical

3.1.3.6 Function Type Identity

Two functions T and U have identical type if and only if

- T and U have the same number of input and output elements
- For each input or output element
 - The corresponding elements have the same name
 - The corresponding elements are ordered type identical

3.1.3.7 Enumeration Type Equivalence

Two enumeration types S and E are equivalent if:

- S and E have the same number of enumeration literals
- the *i*:th enumeration literal of S has the same name as the *i*:th enumeration literal of E.

3.1.3.8 Subtyping of enumeration types

For any enumeration types S and E, S is a supertype of E and E is a subtype of S if they are equivalent or if:

- every enumeration literal of S also exists in E and
- the *i*:th enumeration literal of S has the same name as the *i*:th enumeration literal of E.

3.1.4 External representation of classes

Classes may be represented in the hierarchical structure of the operating system [*the file system or a database*]. The nature of such an external entity falls into one of the following two groups:

- Structured entities [*e.g. a directory in the file system*]
- Non-structured entities [*e.g. a file in the file system*]

3.1.4.1 Structured entities

A structured entity [*e.g. the directory A*] shall contain a node. In a file hierarchy, the node shall be stored in file `package.mo`. The node shall contain a stored-definition that defines a class *[A]* with a name matching the name of the structured entity. [*The node typically contains documentation and graphical information for a package, but may also contain additional elements of the class A.*]

A structured entity may also contain one or more sub-entities (structured or non-structured). The sub-entities are mapped as elements of the class defined by their enclosing structured entity. [*For example, if directory A contains the three files `package.mo`, `B.mo` and `C.mo` the classes defined are A, A.B, and A.C.*] Two sub-entities shall not define classes with identical names [*for example, a directory shall not contain both the sub-directory A and the file A.mo*].

3.1.4.2 Non-structured entities

A non-structured entity [*e.g. the file A.mo*] shall contain only a model-definition that defines a class *[A]* with a name matching the name of the non-structured entity.

3.1.4.3 Within clause

A non-top level entity shall begin with a within-clause which for the class defined in the entity specifies the location in the Modelica class hierarchy. A top-level class may contain a within-clause with no name.

For a sub-entity of an enclosing structured entity, the within-clause shall designate the class of the enclosing entity.

3.1.4.4 Use of MODELICAPATH

The top-level scope implicitly contains a number of classes stored externally. If a top-level name is not found at global scope, a Modelica translator shall look up additional classes in an ordered list of library roots, called MODELICAPATH. *[On a typical system, MODELICAPATH is an environment variable containing a semicolon-separated list of directory names.]*

[The first part of the path A.B.C (i.e., A) is located by searching the ordered list of roots in MODELICAPATH. If no root contains A the lookup fails. If A has been found in one of the roots, the rest of the path is located in A; if that fails, the entire lookup fails without searching for A in any of the remaining roots in MODELICAPATH.]

3.2 Declarations

3.2.1 Component clause

If the type specifier of the component denotes a built-in type (RealType, IntegerType, etc.), the instantiated component has the same type.

If the type specifier of the component does not denote a built-in type, the name of the type is looked up (3.1.1). The found type is instantiated with a new environment and the partially instantiated parent of the component. It is an error if the type is partial. The new environment is the result of merging

- the modification of parent element-modification with the same name as the component
- the modification of the component declaration

in that order.

An environment that defines the value of a component of built-in type is said to define a declaration equation associated with the declared component. For declarations of vectors and matrices, declaration equations are associated with each element. *[This makes it possible to override the declaration equation for a single element in a parent modification, which would not be possible if the declaration equation is regarded as a single matrix equation.]*

Array dimensions shall be non-negative parameter expressions, or the colon operator denoting that the array dimension is left unspecified.

Variables declared with the **flow** type prefix shall be a subtype of Real.

Type prefixes (i.e., flow, discrete, parameter, constant, input, output) shall only be applied for type, record and connector components. The type prefixes flow, input and output of a structured component are also applied to the elements of the component. The type prefixes flow, input and output shall only be applied for a structured component, if no element of the component has a corresponding type prefix of the same category. *[For example, input can only be used, if none of the elements has an input or output type prefix].* The corresponding rules for the type prefixes discrete, parameter and constant are described in section 3.2.2.1.

The rules for components of function types and components in functions are described in section 3.2.13.

3.2.2 Variability prefix

The prefixes **discrete**, **parameter**, **constant** of a component declaration are called *variability prefixes* and define in which situation the variable values of a component are initialized (see section 3.5) and when they are changed

in *transient* analysis (= solution of initial value problem of the hybrid DAE):

- A variable `vc` declared with the **parameter** or **constant** prefixes remains constant during transient analysis.
- A **discrete-time** variable `vd` has a vanishing time derivative (informally $\text{der}(vd)=0$, but it is not legal to apply the `der()` operator to discrete-time variables) and can change its values only at event instants during transient analysis (see section 3.5).
- A **continuous-time** variable `vn` may have a non-vanishing time derivative ($\text{der}(vn)\neq 0$ possible) and may change its value at any time during transient analysis (see section 3.5).

If a Real variable is declared with the prefix **discrete** it must be assigned in a when-clause, either by an assignment or an equation.

A Real variable assigned in a when-clause is a discrete-time variable, even though it was not declared with the prefix **discrete**. A Real variable not assigned in any when-clause and without any type prefix is a continuous-time variable.

The default variability for Integer, String, or Boolean variables is discrete-time, and it is not possible to declare continuous-time Integer, String, or Boolean variables. *[A Modelica translator is able to guarantee this property due to restrictions imposed on discrete expressions, see section 3.4.9]*

The variability of expressions and restrictions on variability for definition equations is given in section 3.4.9.

*[A **discrete-time** variable is a piecewise constant signal which changes its values only at event instants during simulation. Such types of variables are needed in order that special algorithms, such as the algorithm of Pantelides for index reduction, can be applied (it must be known that the time derivative of these variables is identical to zero). Furthermore, memory requirements can be reduced in the simulation environment, if it is known that a component can only change at event instants.*

*A **parameter** variable is constant during simulation. This prefix gives the library designer the possibility to express that the physical equations in a library are only valid if some of the used components are constant during simulation. The same also holds for **discrete-time** and **constant** variables. Additionally, the **parameter** prefix allows a convenient graphical user interface in an experiment environment, to support quick changes of the most important constants of a compiled model. In combination with an **if**-clause, a **parameter** prefix allows to remove parts of a model before the symbolic processing of a model takes place in order to avoid variable causalities in the model (similar to `#ifdef` in C). Class parameters can be sometimes used as an alternative. Example:*

```

model Inertia
  parameter Boolean state = true;
  ...
equation
  J*a = t1 - t2;
  if state then      // code which is removed during symbolic
    der(v) = a;      // processing, if state=false
    der(r) = v;
  end if;
end Inertia;

```

*A **constant** variable is similar to a parameter with the difference that constants cannot be changed after they have been given a value. It can be used to represent mathematical constants, e.g.*

```

constant Real PI=4*arctan(1);

```

There are no continuous-time Boolean, Integer or String variables. In the rare cases they are needed they can be faked by using Real variables, e.g.:

```

Boolean off1, off1a;
Real off2;
equation
  off1 = s1 < 0;
  off1a = noEvent(s1 < 0); // error, since off1a is discrete
  off2 = if noEvent(s2 < 0) then 1 else 0; // possible
  u1 = if off1 then s1 else 0; // state events
  u2 = if noEvent(off2 > 0.5) then s2 else 0; // no state events

```

Since *off1* is a **discrete-time** variable, state events are generated such that *off1* is only changed at event instants. Variable *off2* may change its value during continuous integration. Therefore, *u1* is guaranteed to be continuous during continuous integration whereas no such guarantee exists for *u2*.

]

3.2.2.1 Variability of structured entities

For elements of structured entities with variability prefixes the most restrictive of the variability prefix and the variability of the component wins (using the default variability for the component if there is no variability prefix on the component).

[Example:

```

record A
  constant Real pi=3.14;
  Real y;
  Integer i;
end A;
parameter A a;
  // a.pi is a constant
  // a.y and a.i are parameters
  A b;
  // b.pi is a constant
  // b.y is a continuous-time variable
  // b.i is a discrete-time variable

```

]

3.2.3 Parameter bindings

The declaration equations for parameters and constants in the translated model must be acyclical after instantiation. Thus it is not possible to introduce equations for parameters by cyclic dependencies.

[Example:

```

constant Real p=2*q;
constant Real q=sin(p); // Illegal since p=2*q, q=sin(p) are cyclical

model ABCD
  parameter Real A[n,n];
  parameter Integer n=size(A,1);
end ABCD;

```

```

final ABCD a;
// Illegal since cyclic dependencies between size(a.A,1) and a.n

ABCD b(redeclare Real A[2,2]=[1,2;3,4]);
// Legal since size of A is no longer dependent on n.

ABCD c(n=2); // Legal since n is no longer dependent on the size of A.
]

```

3.2.4 Protected elements

Protected element cannot be accessed via dot notation. They may not be modified or redeclared in class modification.

All elements defined under the heading **protected** are regarded as protected. All other elements [*i.e.*, defined under the heading **public**, without headings or in a separate file] are public [*i.e.* not protected].

If an extends clause is used under the **protected** heading, all elements of the base class become protected elements of the current class. If an extends clause is a public element, all elements of the base class are inherited with their own protection. The eventual headings **protected** and **public** from the base class do not affect the consequent elements of the current class (*i.e.* headings **protected** and **public** are not inherited).

3.2.5 Array declarations

The Modelica type system includes scalar number, vector, matrix (number of dimensions, ndim=2), and arrays of more than two dimensions. [*There is no distinguishing between a row and column vector.*]

The following table shows the two possible forms of declarations and defines the terminology. C is a placeholder for any class, including the builtin type classes Real, Integer, Boolean and String:

Modelica form 1	Modelica form 2	# dimensions	Designation	Explanation
C x;	C x;	0	Scalar	Scalar
C[n] x;	C x[n];	1	Vector	n - Vector
C[n, m] x;	C x[n, m];	2	Matrix	n x m Matrix
C[n, m, p,] x;	C x[m, n, p,];	k	Array	Array with k dimensions (k>=0).

[*The number of dimensions and the dimensions sizes are part of the type, and shall be checked for example at redeclarations. Declaration form 1 displays clearly the type of an array, whereas declaration form 2 is the traditional way of array declarations in languages such as Fortran, C, C.*]

```
Real[:] v1, v2 // vectors v1 and v2 have unknown sizes. The actual sizes may be different.
```

It is possible to mix the two declaration forms, but it is not recommended

```
Real[3,2] x[4,5]; // x has type Real[4,5,3,2];
]
```

Zero-valued dimensions are allowed, so $C \times [0]$; declares an empty vector and $C \times [0, 3]$; an empty matrix.

[Special cases:

Modelica form 1	Modelica form 2	# dimensions	Designation	Explanation
$C[1] x;$	$C x[1];$	1	Vector	1 – Vector, representing a scalar
$C[1,1] x;$	$C x[1, 1];$	2	Matrix	1 x 1 – Matrix, representing a scalar
$C[n,1] x;$	$C x[n, 1];$	2	Matrix	n x 1 – Matrix, representing a column
$C[1,n] x;$	$C x[1, n];$	2	Matrix	1 x n – Matrix, representing a row

]

The type of an array of array is the multidimensional array which is constructed by taking the first dimensions from the component declaration and subsequent dimensions from the maximally expanded component type. A type is maximally expanded, if it is either one of the built-in types (Real, Integer, Boolean, String) or it is not a type class. Before operator overloading is applied, a type class of a variable is maximally expanded.

[Example:

```

type Voltage = Real(unit = "V");
type Current = Real(unit = " A ");
connector Pin
  Voltage v;           // type class of v = Voltage, type of v = Real
  flow Current i;     // type class of i = Current, type of i = Real
end Pin;
type MultiPin = Pin[5];

MultiPin[4] p;        // type class of p is MultiPin, type of p is Pin[4,5];

type Point = Real[3];
Point p1[10];
Real p2[10,3];

```

The components *p1* and *p2* have identical types.

```

p2[5] = p1[2] + p2[4]; // equivalent to p2[5,:] = p1[2,:] + p2[4,:]
Real r[3] = p1[2];    // equivalent to r[3] = p1[2,:]

```

]

[Automatic assertions at simulation time:

Let *A* be a declared array and *i* be the declared maximum dimension size of the d_i -dimension, then an assert statement “assert(*i* >= 0, ...)” is generated provided this assertion cannot be checked at compile time. It is a quality of implementation issue to generate a good error message if the assertion fails.

Let *A* be a declared array and *i* be an index accessing an index of the d_i -dimension. Then for every such index-access an assert statement “assert(*i* >= 1 and *i* <= size(*A*,*d_i), ...)” is generated, provided this assertion cannot be checked at compile time.*

For efficiency reasons, these implicit assert statement may be optionally suppressed.]

3.2.6 Final element modification

An element defined as **final** in an element modification or declaration cannot be modified by a modification or by a redeclaration. All elements of a **final** element are also **final**. *[Setting the value of a parameter in an experiment environment is conceptually treated as a modification. This implies that a final modification equation of a parameter cannot be changed in a simulation environment].*

[Examples:

```

type Angle = Real(final quantity="Angle", final unit = "rad",
                  displayUnit="deg");
Angle a1(unit="deg");           // error, since unit declared as final!
Angle a2(displayUnit="rad");   // fine

```

```

model TransferFunction
  parameter Real b[:] = {1} "numerator coefficient vector";
  parameter Real a[:] = {1,1} "denominator coefficient vector";
  ...
end TransferFunction;

```

```

model PI "PI controller";
  parameter Real k=1 "gain";
  parameter Real T=1 "time constant";
  TransferFunction tf(final b=k*{T,1}, final a={T,0});
end PI;

```

```

model Test
  PI c1(k=2, T=3); // fine
  PI c2(b={1});   // error, b is declared as final
end Test;

```

]

3.2.7 Short class definition

A class definition of the form

```

class IDENT1 = IDENT2 class_modification ;

```

is identical, except for the lexical scope of modifiers, where the short class definition does not introduce an additional lexical scope for modifiers, to the longer form

```

class IDENT1
  extends IDENT2 class_modification ;
end IDENT1;

```

[Example: demonstrating the difference in scopes:

```

model Resistor
  parameter Real R;
  ...
end Resistor;

```

```

model A
  parameter Real R;
  replaceable model Load=Resistor(R=R) extends TwoPin;
  // Correct, sets the R in Resistor to R from model A.

  replaceable model LoadError
    extends Resistor(R=R);
  // Gives the singular equation R=R, since the right-hand side R
  // is searched for in LoadError and found in its base-class Resistor.
  end LoadError extends TwoPin;
  Load a,b,c;
  ConstantSource ...;
  ....
end A;
]

```

A short class definition of the form

```
type TN = T[N] (optional modifier) ;
```

where N represents arbitrary array dimensions, conceptually yields an array class

```

'array' TN
  T[n] _ (optional modifiers);
'end' TN;

```

Such an array class has exactly one anonymous component (`_`). When a component of such an array class type is instantiated, the resulting instantiated component type is an array type with the same dimensions as `_` and with the optional modifier applied.

[Example:

```

type Force = Real[3] (unit={"Nm", "Nm", "Nm"});
Force f1;
Real f2[3] (unit={"Nm", "Nm", "Nm"});

```

the types of f1 and f2 are identical.]

A base-prefix applied in the short-class definition does not influence its type, but is applied to components declared of this type or types derived from it. It is not legal to combine other components with an `extends` from an array class, a class with non-empty base-prefix, or a simple type.

[Example:

```

type InArgument=input Real;
type OutArgument=output Real[3];
function foo

```

```

    InArgument u; // Same as 'input Real u'
    OutArgument y; // Same as 'output Real[3] y'
algorithm
  y:=fill(u,3);
end foo;
  Real x[:]=foo(time);
]

```

3.2.7.1 Enumeration types

A declaration of the form

```
type E = enumeration([enum_list]);
```

defines an enumeration type E and the associated enumeration literals of the enum-list. This is the only legal use of the enumeration keyword. The enumeration literals shall be distinct within the enumeration type. The names of the enumeration literals are defined inside the scope of E. Each enumeration literal in the enum_list has type E.

[Example:

```

type Size = enumeration(small, medium, large, xlarge);
  Size t_shirt_size = Size.medium;

```

].

An enumeration type is a simple type and the attributes are defined in section 3.6.

[Example:

```

type DigitalCurrentChoices = enumeration(zero, one);
  // Similar to Real, Integer

```

Setting attributes:

```

type DigitalCurrent = DigitalCurrentChoices(quantity="Current",
                                             start = one, fixed = true);
  DigitalCurrent c(start = DigitalCurrent.one, fixed = true);
  DigitalCurrentChoices c(start = DigitalCurrentChoices.one, fixed = true);

```

]

Local class definition

The local class should be statically instantiable with the partially instantiated parent of the local class apart from local class components that are partial or outer. The environment is the modification of any parent class element modification with the same name as the local class, or an empty environment.

The uninstantiated local class together with its environment becomes an element of the instantiated parent class.

[The following example demonstrates parameterization of a local class:

```

class C1
  class Voltage = Real(nominal=1);
  Voltage v1, v2;
end C1;
class C2
  extends C1(Voltage(nominal=1000));

```

```
end C2;
```

Instantiation of class C2 yields a local class Voltage with nominal-modifier 1000. The variables v1 and v2 instantiate this local class and thus have a nominal value of 1000.]

3.2.9 Extends clause

The name of the base class is looked up in the partially instantiated parent of the extends clause. The found base class is instantiated with a new environment and the partially instantiated parent of the extends clause. The new environment is the result of merging

1. arguments of all parent environments that match names in the instantiated base class
2. the optional class modification of the extends clause

in that order.

[Examples of the three rules are given in the following example:

```
class A
  parameter Real a, b;
end A;
class B
  extends A(b=2);      // Rule #2
end B;
class C
  extends B(a=1);     // Rule #1
end C;
```

]

The elements of the instantiated base class become elements of the instantiated parent class.

[From the example above we get the following instantiated class:

```
class Cinstance
  parameter Real a=1;
  parameter Real b=2;
end Cinstance;
```

The ordering of the merging rules ensures that, given classes A and B defined above,

```
class C2
  B bcomp(b=3);
end C2;
```

yields an instance with bcomp.b=3, which overrides b=2.]

The declaration elements of the instantiated base class shall either

- Not already exist in the partially instantiated parent class *[i.e., have different names]* .
- Be exactly identical to any element of the instantiated parent class with the same name and the same level of protection (**public** or **protected**) and same contents. In this case, one of the elements is ignored (since they are identical it does not matter which one).

Otherwise the model is incorrect.

Equations of the instantiated base class that are syntactically equivalent to equations in the instantiated parent class are discarded. *[Note: equations that are mathematically equivalent but not syntactically equivalent are not*

discarded, hence yield an overdetermined system of equations.]

Redeclaration

A **redeclare** construct replaces the declaration of a local class or component in the modified element with another declaration.

[Example:

```

class A
  parameter Real x;
end A;
class B
  parameter Real x=3.14, y;    // B is a subtype of A
end B;
class C
  replaceable A a(x=1);
end C;
class D
  extends C(redeclare B a(y=2));
end D;

```

which effectively yields a class D2 with the contents

```

class D2
  B a(x=1, y=2);
end D2;

```

]

3.2.10.1 Constraining type

In an replaceable declaration the optional `constraining_clause` define a constraining type. *[It is recommended to not have modifiers in the `constraining_clause`.]* If the `constraining_clause` is not present the type of the declaration is also used as a constraining type.

The class or type of component shall be a subtype of the constraining type. In a redeclaration of a replaceable element the class or type of a component must be a subtype of the constraining type. The constraining type of a replaceable redeclaration must be a subtype of the constraining type of the declaration it redeclares.

In an element modification of a replaceable element the modifications are applied both to the actual type and to the constraining type.

In an element redeclaration of a replaceable element the modifiers of the replaced constraining type is merged to both the new declaration and to the new constraining type, using the normal rules where outer modifiers override inner modifiers.

3.2.10.2 Restrictions on redeclarations

The following additional constraints apply to redeclarations:

- only classes and components declared as replaceable can be redeclared with a new type, which must be a subtype of the constraining type of the original declaration, and to allow further redeclarations one must use “**redeclare replaceable**”
- a replaceable class used in an extends clause shall only contain public components *[otherwise, it cannot be guaranteed that a redeclaration keeps the protected variables of the replaceable default*

class]

- an element declared as **constant** cannot be redeclared
- an element declared as **parameter** can only be redeclared with **parameter** or **constant**
- an element declared as **discrete** can only be redeclared with **discrete**, **parameter** or **constant**
- a **function** can only be redeclared as **function**
- an element declared as **flow** can only be redeclared with **flow**
- an element declared as not **flow** can only be redeclared without **flow**
- an element declared as **input** can only be redeclared as **input**
- an element declared as **output** can only be redeclared as **output**

Modelica does not allow a protected element to be redeclared as public, or a public element to be redeclared as protected.

Array dimensions may be redeclared.

3.2.10.3 Suggested redeclarations and modifications

A declaration can have an annotation "choices" containing modifiers on choice, where each of them indicates a suitable redeclaration or modifications of the element.

This is a hint for users of the model, and can also be used by the user interface to suggest reasonable redeclaration, where the string comments on the choice declaration can be used as textual explanations of the choices. The annotation is not restricted to replaceable elements but can also be applied to non-replaceable elements, enumeration types, and simple variables.

[Example:

```

replaceable model MyResistor=Resistor
  annotation(choices(
    choice(redeclare MyResistor=lib2.Resistor(a={2}) "..."),
    choice(redeclare MyResistor=lib2.Resistor2 "...")));

replaceable Resistor Load(R=2) extends TwoPin
  annotation(choices(
    choice(redeclare lib2.Resistor Load(a={2}) "..."),
    choice(redeclare Capacitor Load(L=3) "...")));

replaceable FrictionFunction a(func=exp) extends Friction
  annotation(choices(
    choice(redeclare ConstantFriction a(c=1) "..."),
    choice(redeclare TableFriction a(table="...") "..."),
    choice(redeclare FunctionFriction a(func=exp) "..."))));

```

It can also be applied to non-replaceable declarations, e.g. to describe enumerations.

```

type KindOfController=Integer(min=1,max=3)
  annotation(choices(
    choice=1 "P",

```

```

        choice=2 "PI",
        choice=3 "PID"));

```

```

model A
  KindOfController x;
end A;
A a(x=3 "PID");
]

```

3.2.11 Derivatives of functions

A function declaration can have an annotation derivative specifying the derivative function with an optional order-attribute indicating the order of the derivative (default 1). This can influence simulation time and accuracy and can be applied to both functions written in Modelica and to external functions.

[Example:

```

function foo0 annotation(derivative=foo1); end foo0;
function foo1 annotation(derivative(order=2)=foo2); end foo1;
function foo2 end foo2;
]

```

The inputs to the derivative function of order 1 are constructed as follows:

First are all inputs to the original function, and after all them we will in order append one derivative for each input containing reals.

The outputs are constructed by starting with an empty list and then in order appending one derivative for each output containing reals.

If the Modelica function call is a n th derivative ($n \geq 1$), i.e. this function call has been derived from an $(n-1)$ th derivative, an annotation($order=n+1$)=..., specifies the $(n+1)$ th derivative, and the $(n+1)$ th derivative call is constructed as follows:

The input arguments are appened with the $(n+1)$ th derivative, which are constructed in order from the n th order derivatives.

The output arguments are similar to the output argument for the n th derivative, but each output is one higher in derivative order.

[Example: Given the declarations

```

function foo0
  ...
  input Real x;
  input Boolean linear;
  input ...;
  output Real y;
  ...
  annotation(derivative=foo1);
end foo0;

function foo1
  ...
  input Real x;
  input Boolean linear;

```

```

input ...;
input Real der_x;
...
output Real der_y;
...
annotation(derivative(order=2)=foo2);
end foo1;

function foo2
...
input Real x;
input Boolean linear;
input ...;
input Real der_x;
...;
input Real der_2_x;
...
output Real der_2_y;
...

```

the equation

$$(\dots,y(t),\dots)=\text{foo0}(\dots,x(t),b,\dots);$$

implies that:

$$(\dots,d y(t)/dt,\dots)=\text{foo1}(\dots,x(t),b,\dots, \dots,d x(t)/dt,\dots);$$

$$(\dots,d^2 y(t)/dt^2,\dots)=\text{foo2}(\dots,x(t),b,\dots,d x(t)/dt,\dots, \dots,d^2 x(t)/dt^2,\dots);$$

]

An input or output to the function may be any simple type (Real, Boolean, Integer, String and enumeration types) or a record, provided the record does not contain both reals and non-reals predefined types. The function must have at least one input containing reals. The output list of the derivative function may not be empty.

3.2.12 Restricted classes

The keyword **class** can be replaced by one of the following keywords: **record**, **type**, **connector**, **model**, **block**, **package** or **function**. Certain restrictions will then be imposed on the content of such a definition. The following table summarizes the restrictions. The predefined types are described in section 3.6.

record	No equations are allowed in the definition or in any of its components. May not be used in connections. May not contain protected components.
type	May only be extension to the predefined types, enumerations, records or array of type.
connector	No equations are allowed in the definition or in any of its components.
model	May not be used in connections.
block	Fixed causality, input-output block. Each component of an interface must either have causality equal to input or output. May not be used in connections.
package	May only contain declarations of classes and constants.

function	Same restrictions as for block. Additional restrictions: no equations, no initial algorithm, at most one algorithm clause. Calling a function requires either an algorithm clause or an external function interface. A function can not contain calls to the Modelica built-in operators der , initial , terminal , sample , pre , edge , change , reinit , delay and cardinality .
-----------------	---

3.2.13 Components of function type

A function can be called, 3.4.8, or a component of function type can be instantiated. It is also possible to modify and extend a function class e.g. to add default values for input variables.

When a function is called components of a function do not have start-attributes, but a binding assignment ("**:=**" expression) is an expression such that the component is initialized to this expression at the start of every function invocation (before executing the algorithm section or calling the external function). Binding assignments can only be used for components of a function. If no binding assignment is given for a non-input component its value at the start of the function invocation is undefined. It is a quality of implementation issue to diagnose this for non-external functions. Binding assignment for input arguments are interpreted as default arguments, as described in section 3.4.8. The size of each non-input array component of a function must be given by the inputs. The enable attribute of each output component of a function must be given by the inputs. Components of a function will inside the function behave as though they had discrete-time variability.

When instantiating a component of function type it behaves as though the following rules were followed:

- All binding assignments in the function to its components are ignored.
- The algorithm/external section of the function component is replaced by

```
equation
  (out1,out2,...)=function call(inp1=inp1,inp2=inp2,...);
```

 where this function call behaves as described above.
- Protected components of the component of function type are ignored, since they are not given a value by the above-mentioned function-call.

[Example:

```
connector InPort = input Real;
connector OutPort = output Real;
function sin
  input InPort u;
  output OutPort y;
  protected Real x;
  external "C";
  annotation(...);
end sin;
```

It can then be used as:

```
Real y=sin(time); // Direct call
sin sin1; // Component of function type
Clock clock;
equation
  connect(clock.y, sin1.u); // Connect to the object.
  // Can use: sin1.y,
  // Cannot use: sin1.x since x is protected and thus ignored
```

This can be called as a normal function and since InPort/OutPort are connectors we can also connect to components of the function type.

]

3.3 Equations and Algorithms

3.3.1 Equation and Algorithm clauses

The instantiated equation or algorithm is identical to the non-instantiated equation or algorithm.

Names in an equation or algorithm shall be found by looking up in the partially instantiated parent of the equation or algorithm.

Equation equality = shall not be used in an algorithm clause. The assignment operator := shall not be used in an equation clause.

3.3.2 If clause

The expression of an **if** and **elseif**-clause must be scalar boolean expression. One **if**-clause, and zero or more **elseif**-clauses, and an optional **else**-clause together form a list of branches. One or zero of the bodies of these **if**-, **elseif**- and **else**-clauses is selected, by evaluating the conditions of the **if**- and **elseif**-clauses sequentially until a condition that evaluates to true is found. If none of the conditions evaluate to true the body of the **else**-clause is selected (if an **else**-clause exists, otherwise no body is selected). In an algorithm section, the selected body is then executed. In an equation section, the equations in the body are seen as equations that must be satisfied. The bodies that are not selected have no effect on that model evaluation.

If clauses in **equation** sections which do not have exclusively parameter expressions as switching conditions shall have an **else** clause and each branch shall have the *same number of equations*. *[If this condition is violated, the single assignment rule would not hold, because the number of equations may change during simulation although the number of unknowns remains the same].*

3.3.3 For clause

A clause

```
for IDENT in expression loop
```

is one example of a for clause.

The expression of a for clause shall be a vector expression. It is evaluated once for each for clause, and is evaluated in the scope immediately enclosing the for clause. In an equation section, the expression of a for clause shall be a parameter expression. The loop-variable is in scope inside the loop-construct and shall not be assigned to.

[Example:

```
for i in 1:10 loop           // i takes the values 1,2,3,...,10
for r in 1.0 : 1.5 : 5.5 loop // r takes the values 1.0, 2.5, 4.0, 5.5
for i in {1, 3, 6, 7} loop   // i takes the values 1, 3, 6, 7
```

The loop-variable may hide other variables as in the following example. Using another name for the loop-variable is, however, strongly recommended.

```

    constant Integer j=4;
    Real x[j];
equation
  for j in 1:j loop // The loop-variable j takes the values 1,2,3,4
    x[j]=j; // Uses the loop-variable j
  end for;
]

```

3.3.3.1 Deduction of ranges

An iterator IDENT **in** range-expr without the '**in** range-expr' requires that the IDENT appear as *the subscript* of one or several subscripted expressions. The dimension size of the array expression in the indexed position is used to deduce the range-expr as 1:size(array-expression,indexpos). If it is used to subscript several expressions, their ranges must be identical. The IDENT may also, inside a reduction-expression, array constructor expression, or for-clause, occur freely outside of subscript positions, but only as a reference to the variable IDENT, and not for deducing ranges.

[Example:

```

    Real xsquared[:]={x[i]*x[i] for i};
    // Same as: {x[i]*x[i] for i in 1:size(x,1)}
    Real xsquared2[size(x,1)];
equation
  for i loop // Same as: for i in 1:size(x,1) loop ...
    xsquared2[i]=x[i]^2;
  end for;
]

```

3.3.3.2 Several iterators

The notation with several iterators is a shorthand notation for nested for-clauses (or reduction-expressions). For for-clauses it can be expanded into the usual form by replacing each "," by 'loop for' and adding extra 'end for'. For reduction-expressions it can be expanded into the usual form by replacing each ',' by ') for' and prepending the reduction-expression with 'function-name ('.

[Example:

```

    Real x[4,3];
equation
  for j, i in 1:2 loop
    // The loop-variable j takes the values 1,2,3,4 (due to use)
    // The loop-variable i takes the values 1,2 (given range)
    x[j,i]=j+i;
  end for;
]

```

3.3.4 When clause

The expression of a when clause shall be a discrete-time Boolean scalar or vector expression. The equations and algorithm statements within a when clause are activated when the scalar or any one of the elements of the vector expression becomes true. When-clauses in equation sections are allowed, provided the equations within the when-clause have one of the following forms:

- `v = expr;`
- `(out1, out2, out3, ...) = function_call(in1, in2, ...);`
- operators `assert()`, `terminate()`, `reinit()`
- **For** and **if**-clause if the equations within the **for** and **if**-clauses satisfy these requirements.
- In an equation section, the different branches of when/elsewhen must have the same set of component references on the left-hand side.
- In an equation section, the branches of an if-then-else clause inside when-clauses must have the same set of component references on the left-hand side, unless the if-then-else have exclusively parameter expressions as switching conditions.

A when clause shall not be used within a function class.

[Example:

Algorithms are activated when x becomes > 2 :

```

when x > 2 then
  y1 := sin(x);
  y3 := 2*x + y1+y2;
end when;

```

Algorithms are activated when either x becomes > 2 or `sample(0,2)` becomes true or x becomes less than 5:

```

when {x > 2, sample(0,2), x < 5} then
  y1 := sin(x);
  y3 := 2*x + y1+y2;
end when;

```

For when in equation sections the order between the equations does not matter, e.g.

```

equation
  when x > 2 then
    y3 = 2*x +y1+y2; // Order of y1 and y3 equations does not matter
    y1 = sin(x);
  end when;
  y2 = sin(y1);

```

The needed restrictions on equations within a when-clause becomes apparent with the following example:

```

  Real x, y;
  equation
    x + y = 5;
    when condition then
      2*x + y = 7;           // error: not valid Modelica
    end when;

```

When the equations of the when-clause are not activated it is not clear which variable to hold constant, either x or y . A corrected version of this example is:

```

  Real x,y;
  equation
    x + y = 5;
    when condition then

```

```

    y = 7 - 2*x;          // fine
  end when;

```

Here, variable y is held constant when the when-clause is de-activated and x is computed from the first equation using the value of y from the previous event instant.

For when in algorithm sections the order is significant and it is advisable to have only one assignment within the when-clause and instead use several algorithms having when-clauses with identical conditions, e.g..

```

algorithm
  when x > 2 then
    y1 := sin(x);
  end when;
equation
  y2 = sin(y1);
algorithm
  when x > 2 then
    y3 := 2*x + y1 + y2;
  end when;

```

Merging the when-clauses can lead to less efficient code and different models with different behaviour depending on the order of the assignment to $y1$ and $y3$ in the algorithm.]

A when clause

```

algorithm
  when {x>1, ..., y>p} then
    ...
  elseif x > y.start then
    ...
  end when;

```

is equivalent to the following special if-clause, where Boolean $b1[N]$; and Boolean $b2$ are necessary because the `edge()` operator can only be applied to variables

```

Boolean b1[N] (start={x.start>1, ..., y.start>p});
Boolean b2 (start=x.start>y.start);
algorithm
  b1:={x>1, ..., y>p};
  b2:=x>y.start;

  if edge(b1[1]) or edge(b1[2]) or ... edge(b1[N]) then
    ...
  elseif edge(b2) then
    ...
  end if;

```

with “`edge(A) = A and not pre(A)`” and the additional guarantee, that the algorithms within this special if clause are only evaluated at event instants.

A when-clause

```

equation
  when x>2 then

```

```

    v1 = expr1;
    v2 = expr2;
  end when;

```

is equivalent to the following special if-expressions

```

  Boolean b(start=x.start>2);
  equation
    b = x>2;
    v1 = if edge(b) then expr1 else pre(v1);
    v2 = if edge(b) then expr2 else pre(v2);

```

The start-values of the introduced boolean variables are defined by the taking the start-value of the when-condition, as above where p is a parameter variable. The start-values of the special functions **initial**, **terminal**, and **sample** is false.

When clauses cannot be nested.

[Example:

The following when clause is invalid:

```

  when x > 2 then
    when y1 > 3 then
      y2 = sin(x);
    end when;
  end when;

```

]

3.3.5 While clause

The expression of a while clause shall be a scalar boolean expression. The while-clause corresponds to while-statements in programming languages, and is formally defined as follows

1. The expression of the while clause is evaluated.
2. If the expression of the while-clause is false, the execution continues after the while-clause.
3. If the expression of the while-clause if true, the entire body of the while clause is executed, and then execution proceeds at step 1.

3.3.6 Connections

Connections between objects are introduced by the **connect** statement in the equation part of a class. The **connect** construct takes two references to connectors, each of which is either an element of the same class as the **connect** statement or an element of one of its components. If the connect construct references array of connectors, the array dimensions must match, and each corresponding pair of elements from the arrays is connected as a pair of scalar connectors.

[Example of array use:

```

connector InPort=input Real;
connector OutPort=output Real;
block MatrixGain
  input InPort u[size(A,1)];
  output OutPort y[size(A,2)]
  parameter Real A[:,:]=[1];
  equation
    y=A*u;
  end MatrixGain;

sin sinSource[5];
MatrixGain gain(A=5*identity(5));
MatrixGain gain2(A=ones(5,2));
OutPort x[2];
equation
  connect(sinSource.y, gain.u); // Legal
  connect(gain.y, gain2.u); // Legal
  connect(gain2.y, x); // Legal
]

```

The two main tasks are to:

- Build connection sets from **connect** statements.
- Generate equations for the complete model.

Definitions:

Connection sets

A connection set is a set of variables connected by means of connect clauses. A connection set shall contain either only flow variables or only non-flow variables.

Inside and outside connectors

In an element instance M, each connector element of M is called an outside connector with respect to M. All other connector elements that are hierarchically inside M, but not in one of the outer connectors of M, is called an inside connector with respect to M.

[Example: in connect(a,b,c) 'a' is an outside connector and 'b,c' is an inside connector, unless 'b' is a connector.]

3.3.6.1 Generation of connection equations

Before generating connection equations **outer** elements are resolved to the corresponding **inner** elements in the instance hierarchy (see Dynamic name lookup 3.1.1.3). The arguments to each connect-statement are resolved to two connector elements, and the connection is moved up zero or more times in the instance hierarchy to the first element instance that both the connectors are hierarchically contained in it.

For every use of the connect statement

```
connect(a, b);
```

the primitive components of a and b form a connection set. If any of them already occur in a connection set from previous connections with matching inside/outside, these sets are merged to form one connection set. Composite connector types are broken down into primitive components. Each connection set is used to generate equations for across and through (zero-sum) variables of the form

$$\begin{aligned} a_1 &= a_2 = \dots = a_n; \\ z_1 + z_2 + (-z_3) + \dots + z_n &= \mathbf{0}; \end{aligned}$$

In order to generate equations for through variables [using the *flow prefix*], the sign used for the connector variable z_i above is +1 for inside connectors and -1 for outside connectors [z_3 in the example above].

For each flow (zero-sum) variable in a connector that is not connected as an inside connector in any element instance the following equation is implicitly generated:

$$z = \mathbf{0};$$

The bold-face $\mathbf{0}$ represents an array or scalar zero of appropriate dimensions (i.e. the same size as z).

3.3.6.2 Restrictions

A component of a connector declared with the **input** type prefix shall not occur as inside connector in more than one **connect** statement. A component of a connector declared with the **output** type prefix shall not occur as outside connector in more than one **connect** statement. If two components declared with the **input** type prefix are connected in a **connect** statement one must be an inside connector and the other an outside connector. If two components declared with the **output** type prefix are connected in a **connect** statement one must be an inside connector and the other an outside connector.

Subscripts in a connector reference shall be constant expressions.

If the array sizes do not match, the original variables are filled with one-sized dimensions from the left until the number of dimensions match before the connection set equations are generated.

Constants or parameters in connected components yield the appropriate assert statements; connections are not generated.

3.3.7 Initialization

Before any operation is carried out with a Modelica model [e.g., *simulation or linearization*], initialization takes place to assign consistent values for all variables present in the model. During this phase, also the derivatives, **der**(..), and the **pre**-variables, **pre**(..), are interpreted as unknown algebraic variables. The initialization uses all equations and algorithms that are utilized in the intended operation [such as *simulation or linearization*]. The equations of a **when** clause are active during initialization, if and only if they are explicitly enabled with the "**initial**()" operator. In this case, the **when**-clause equations remain active during the whole initialization phase. [If a when-clause equation " $v = \text{expr};$ " is not active during the initialization phase, the equation " $v = \text{pre}(v)$ " is added for initialization. This follows from the mapping rule of when-clause equations].

Further constraints, necessary to determine the initial values of all variables, can be defined in the following ways:

- As equations in an "**initial equation**" section or as assignments in an "**initial algorithm**" section. The equations and assignments in these initial sections are purely algebraic, stating constraints between the variables at the initial time instant. It is not allowed to use **when**-clauses in these sections.
- Implicitly by using the attributes **start=value** and **fixed=true** in the declaration of variables: For all non-discrete Real variables v , the equation " $v = \text{startExpression}$ " is added to the initialization equations, if "**start = startExpression**" and "**fixed = true**".

For all discrete variables `vd`, the equation "`pre(vd) = startExpression`" is added to the initialization equations, if "`start = startExpression`" and "`fixed = true`".

For constants and parameters, the attribute `fixed` is by default `true`. For other variables `fixed` is by default `false`.

[A Modelica translator may first transform the continuous equations of a model, at least conceptually, to state space form. This may require to differentiate equations for index reduction, i.e., additional equations and, in some cases, additional unknown variables are introduced. This whole set of equations, together with the additional constraints defined above, should lead to an algebraic system of equations where the number of equations and the number of all variables (including `der(.)` and `pre(.)` variables) is equal. Often, this is a nonlinear system of equations and therefore it may be necessary to provide appropriate guess values (i.e., start values and `fixed=false`) in order to compute a solution numerically.]

It may be difficult for a user to figure out how many initial equations have to be added, especially if the system has a higher index. A tool may add or remove initial equations automatically such that the resulting system is structurally nonsingular. In these cases diagnostics are appropriate since the result is not unique and may not be what the user expects. A missing initial value of a discrete variable which does not influence the simulation result, may be automatically set to the start value or its default without informing the user. For example, variables assigned in a `when`-clause which are not accessed outside of the `when`-clause and where the `pre()` operator is not explicitly used on these variables, do not have an effect on the simulation.

Examples:

Continuous time controller initialized in steady-state:

```
Real y(fixed = false); // fixed=false is redundant
equation
  der(y) = a*y + b*u;
initial equation
  der(y) = 0;
```

This has the following solution at initialization:

```
der(y) = 0;
y = -b/a *u;
```

Continuous time controller initialized either in steady-state or by providing a start value for state `y`:

```
parameter Boolean steadyState = true;
parameter Real y0 = 0 "start value for y, if not steadyState";
Real y;
equation
  der(y) = a*y + b*u;
initial equation
  if steadyState then
    der(y)=0;
  else
    y = y0;
  end if;
```

This can also be written as follows (this form is less clear):

```
parameter Boolean steadyState=true;
```

```

Real y      (start=0, fixed=not steadyState);
Real der_y(start=0, fixed=steadyState) = der(y);
equation
  der(y) = a*y + b*u;

```

Discrete time controller initialized in steady-state:

```

discrete Real y;
equation
  when {initial(), sampleTrigger} then
    y = a*pre(y) + b*u;
  end when;
initial equation
  y = pre(y);

```

This leads to the following equations during initialization:

```

y = a*pre(y) + b*u;
y = pre(y);

```

With the solution:

```

y := (b*u) / (1-a)
pre(y) := y;
]

```

3.4 Expressions

Modelica equations, assignments and declaration equations contain expressions.

Expressions can contain basic operations, +, -, *, /, ^, etc. with normal precedence as defined in the grammar in section 2.2.7. The semantics of the operations is defined for both scalar and array arguments in section 3.4.6.

It is also possible to define functions and call them in a normal fashion. The function call syntax for both normal and named arguments is described in section 3.4.8 and for vectorized calls in section 3.4.6.10. The built-in array functions are given in section 3.4.3 and other built-in operators in section 3.4.2.

3.4.1 Evaluation

A tool is free to solve equations, reorder expressions and to not evaluate expressions if their values do not influence the result (e.g. short-circuit evaluation of boolean expressions). If-statements and if-expressions guarantee that their clauses are only evaluated if the appropriate condition is true, but relational operators generating state or time events will during continuous integration have the value from the most recent event.

[Example. If one wants to guard an expression against evaluation, it should be guarded by an if

```

Boolean v[n];
Boolean b;
Integer I;
equation
  x=v[I] and (I>=1 and I<=n); // Invalid
  x=if (I>=1 and I<=n) then v[I] else false; // Correct

```

To guard square against square root of negative number use noEvent:

```
der(h)=if h>0 then -c*sqrt(h) else 0; // Incorrect
der(h)=if noEvent(h>0) then -c*sqrt(h) else 0; // Correct
```

]

3.4.2 Modelica built-in operators

Built-in operators of Modelica have the same syntax as a function call. However, they do **not** behave as a mathematical function, because the result depends not only on the input arguments but also on the status of the simulation. The following operators are supported (see also the list of array function in section 3.4.3):

der(x)	The time derivative of x. Variable x need to be a subtype of Real, and may not be a discrete-time variable. If x is an array, the operator is applied to all elements of the array. For Real parameters and constants the result is a zero scalar or array of the same size as the variable.
initial()	Returns true during the initialization phase and false otherwise.
terminal()	Returns true at the end of a successful analysis.
smooth(p, expr)	If $p \geq 0$ smooth (p, expr) returns expr and states that expr is p times continuously differentiable, i.e.: expr is continuous in all real variables appearing in the expression and all partial derivatives with respect to all appearing real variables exist and are continuous up to order p. The only allowed types for expr in smooth are: real expressions, arrays of allowed expressions, and records containing only components of allowed expressions. See also section 3.4.2.2.
noEvent(expr)	Real elementary relations within expr are taken literally, i.e., no state or time event is triggered. See also sections 3.4.2.2, and 3.5.
sample(start,interval)	Returns true and triggers time events at time instants "start + i*interval" (i=0,1,...). During continuous integration the operator returns always false. The starting time "start" and the sample interval "interval" need to be parameter expressions and need to be a subtype of Real or Integer.
pre(y)	Returns the "left limit" $y(t^{pre})$ of variable y(t) at a time instant t. At an event instant, $y(t^{pre})$ is the value of y after the last event iteration at time instant t (see comment below). The pre operator can be applied if the following three conditions are fulfilled simultaneously: (a) variable y is a subtype of a simple type, (b) y is a discrete-time expression (c) the operator is not applied in a function class. The first value of pre (y) is determined in the initialization phase. See also section 3.4.2.1.
edge(b)	Is expanded into "(b and not pre(b))" for Boolean variable b. The same restrictions as for the pre operator apply (e.g. not to be used in function classes).
change(v)	Is expanded into "(v <> pre(v))". The same restrictions as for the pre() operator apply.
reinit(x, expr)	Reinitializes state variable x with expr at an event instant. Argument x need to be

	(a) a subtype of Real and (b) the der -operator need to be applied to it. <code>expr</code> need to be an Integer or Real expression. The <code>reinit</code> operator can only be applied once for the same variable <code>x</code> . It can only be applied in the body of a <code>when</code> -clause. See also section 3.4.2.3
assert (condition, message)	The condition shall be true for successful model evaluations. For full description see section 3.4.2.4.
terminate (message)	Successfully terminates the current analysis. For full description see section 3.4.2.5.
abs (v)	Is expanded into “(if v >= 0 then v else -v)”. Argument <code>v</code> needs to be an Integer or Real expression. <i>[Note, outside of a when clause state events are triggered]</i> .
sign (v)	Is expanded into “(if v > 0 then 1 else if v < 0 then -1 else 0)”. Argument <code>v</code> needs to be an Integer or Real expression. <i>[Note, outside of a when clause state events are triggered]</i>
sqrt (v)	Returns the square root of <code>v</code> if <code>v</code> >=0, otherwise an error occurs. Argument <code>v</code> needs to be an Integer or Real expression.
div (x,y)	Returns the algebraic quotient <code>x/y</code> with any fractional part discarded (also known as truncation toward zero). <i>[Note: this is defined for / in C99; in C89 the result for negative numbers is implementation-defined, so the standard function <code>div()</code> must be used.]</i> Result and arguments shall have type Real or Integer If either of the arguments is Real the result is Real otherwise Integer.
mod (x,y)	Returns the integer modulus of <code>x/y</code> , i.e. <code>mod(x,y)=x-floor(x/y)*y</code> . Result and arguments shall have type Real or Integer. If either of the arguments is Real the result is Real otherwise Integer. <i>[Note, outside of a when clause state events are triggered when the return value changes discontinuously. Examples <code>mod(3,1.4)=0.2</code>, <code>mod(-3,1.4)=1.2</code>, <code>mod(3,-1.4)=-1.2</code>]</i>
rem (x,y)	Returns the integer remainder of <code>x/y</code> , such that <code>div(x,y) * y + rem(x,y) = x</code> . Result and arguments shall have type Real or Integer. If either of the arguments is Real the result is Real otherwise Integer. <i>[Note, outside of a when clause state events are triggered when the return value changes discontinuously. Examples <code>rem(3,1.4)=0.2</code>, <code>rem(-3,1.4)=-0.2</code>]</i>
ceil (x)	Returns the smallest integer not less than <code>x</code> . Result and argument shall have type Real. <i>[Note, outside of a when clause state events are triggered when the return value changes discontinuously.]</i>
floor (x)	Returns the largest integer not greater than <code>x</code> . Result and argument shall have type Real. <i>[Note, outside of a when clause state events are triggered when the return value changes discontinuously.]</i>
integer (x)	Returns the largest integer not greater than <code>x</code> . The argument shall have type Real. The result has type Integer. <i>[Note, outside of a when clause state events are triggered when the return value changes discontinuously.]</i>
delay (expr,delayTime,delayMax)	Returns " <code>expr(time - delayTime)</code> " for

delay (expr,delayTime)	time > time.start + delayTime and "expr(time.start)" for time <= time.start + delayTime. The arguments, i.e., expr, delayTime and delayMax, need to be subtypes of Real. DelayMax needs to be additionally a parameter expression. The following relation shall hold: 0 <= delayTime <= delayMax, otherwise an error occurs. If delayMax is not supplied in the argument list, delayTime need to be a parameter expression. See also section 3.4.2.7.
cardinality (c)	Returns the number of (inside and outside) occurrences of connector instance c in a connect statement as an Integer number. See also section 3.4.2.8.

3.4.2.1 pre

A new event is triggered if at least for one variable v “**pre**(v) \diamond v ” after the active model equations are evaluated at an event instant. In this case the model is at once reevaluated. This evaluation sequence is called “*event iteration*”. The integration is restarted, if for all v used in **pre**-operators the following condition holds: “**pre**(v) == v ”.

*[If v and **pre**(v) are only used in when clauses, the translator might mask event iteration for variable v since v cannot change during event iteration. It is a “quality of implementation” to find the minimal loops for event iteration, i.e., not all parts of the model need to be reevaluated.]*

The language allows mixed algebraic systems of equations where the unknown variables are of type Real, Integer or Boolean. These systems of equations can be solved by a global fix point iteration scheme, similarly to the event iteration, by fixing the Boolean and Integer unknowns during one iteration. Again, it is a quality of implementation to solve these systems more efficiently, e.g., by applying the fix point iteration scheme to a subset of the model equations.]

3.4.2.2 noEvent and smooth

The noEvent operator implies that real elementary expressions are taken literally instead of generating crossing functions, section 3.5. The smooth operator should be used instead of noEvent, in order to avoid events for efficiency reasons. A tool is free to not generate events for expressions inside smooth. However, smooth does not guarantee that no events will be generated, and thus it can be necessary to use noEvent inside smooth. *[Note that smooth does not guarantee a smooth output if any of the occurring variables change discontinuously.]*

[Example:

```
Real x,y,z;
parameter Real p;
equation
  x = if time<1 then 2 else time-2;
  z = smooth(0, if time<0 then 0 else time);
  y = smooth(1, noEvent(if x<0 then 0 else sqrt(x)*x));
  // noEvent is necessary.
```

]

3.4.2.3 reinit

The **reinit** operator does not break the single assignment rule, because **reinit**(x ,expr) makes the previously known state variable x unknown and introduces the equation “ $x = \text{expr}$ ”.

[If a higher index system is present, i.e. constraints between state variables, some state variables need to be

redefined to non-state variables. If possible, non-state variables should be chosen in such a way that states with an applied **reinit** operator are not utilized. If this is not possible, an error occurs, because the reinit operator is applied on a non-state variable.

Example for the usage of the **reinit** operator:

```
Bouncing ball:
  der(h) = v;
  der(v) = -g;

  when h < 0 then
    reinit(v, -e*v);
  end when;
]
```

3.4.2.4 assert

A statement

```
assert(condition, message);
```

is an assert-statement, where condition is a boolean expression and message is a string expression.

If the condition of an assert statement is true, message is not evaluated and the procedure call is ignored. If the condition evaluates to false the current evaluation is aborted. The simulation may continue with another evaluation.

Failed assertions takes precedence over successful termination, such that if the model first triggers the end of successful analysis by reaching the stop-time or explicitly with terminate(), but the evaluation with terminal()=true triggers an assert, the analysis failed. [The intent is to perform a test of model validity and to report the failed assertion to the user if the expression evaluates to false. The means of reporting a failed assertion are dependent on the simulation environment. The intention is that the current evaluation of the model should stop when an assert with a false condition is encountered, but the tool should continue the current analysis (e.g. by using a shorter stepsize).]

3.4.2.5 terminate

The terminate function successfully terminates the analysis which was carried out, see also section **Fehler! Verweisquelle konnte nicht gefunden werden.** The function has a string argument indicating the reason for the success. [The intention is to give more complex stopping criteria than a fixed point in time. Example:

```
model ThrowingBall
  Real x(start=0);
  Real y(start=1);
equation
  der(x)=...
  der(y)=...
algorithm
  when y<0 then
    terminate("The ball touches the ground");
```

```

    end when;
end ThrowingBall;
]

```

3.4.2.6 Event triggering operators

[The *div*, *rem*, *mod*, *ceil*, *floor*, *integer*, *abs* and *sign* operator trigger state events if used outside of a *when* clause. If this is not desired, the *noEvent* function can be applied to them. E.g. *noEvent(abs(v))* is $|v|$

3.4.2.7 delay

The *delay* operator allows a numerical sound implementation by interpolating in the (internal) integrator polynomials, as well as a more simple realization by interpolating linearly in a buffer containing past values of expression *expr*. Without further information, the complete time history of the delayed signals need to be stored, because the delay time may change during simulation. To avoid excessive storage requirements and to enhance efficiency, the maximum allowed delay time has to be given via *delayMax*. This gives an upper bound on the values of the delayed signals which have to be stored. For realtime simulation where fixed step size integrators are used, this information is sufficient to allocate the necessary storage for the internal buffer before the simulation starts. For variable step size integrators, the buffer size is dynamic during integration. In principal, a delay operator could break algebraic loops. For simplicity, this is not supported because the minimum delay time has to be give as additional argument to be fixed at compile time. Furthermore, the maximum step size of the integrator is limited by this minimum delay time in order to avoid extrapolation in the delay buffer.

3.4.2.8 cardinality

The *cardinality* operator allows the definition of connection dependent equations in a model, for example:

```

connector Pin
  Real    v;
  flow Real i;
end Pin;

model Resistor
  Pin p, n;
equation
  // Handle cases if pins are not connected
  if cardinality(p) == 0 and cardinality(n) == 0 then
    p.v = 0; n.v = 0;
  elseif cardinality(p) == 0 then
    p.i = 0;
  elseif cardinality(n) == 0 then
    n.i = 0;
  end if;

  // Equations of resistor
  ...
end Resistor;
]

```

3.4.3 Vectors, Matrices, and Arrays Built-in Functions for Array Expressions

The following function *cannot* be used in Modelica, but is utilized below to define other operators

promote(A,n)	Fills dimensions of size 1 from the right to array A upto dimension n, where "n >= ndims(A)" is required. Let C = promote(A,n), with nA=ndims(A), then ndims(C) = n, size(C,j) = size(A,j) for 1 <= j <= nA, size(C,j) = 1 for nA+1 <= j <= n, C[i_1, ..., i_nA, 1, ..., 1] = A[i_1, ..., i_nA]
---------------------	---

[Function promote could not be used in Modelica, because the number of dimensions of the return array cannot be determined at compile time if n is a variable. Below, promote is only used for constant n].

The following built-in functions for array *expressions* are provided:

Modelica	Explanation
ndims(A)	Returns the number of dimensions k of array expression A, with k >= 0.
size(A,i)	Returns the size of dimension i of array expression A where i shall be > 0 and <= ndims(A).
size(A)	Returns a vector of length ndims(A) containing the dimension sizes of A.
scalar(A)	Returns the single element of array A. size(A,i) = 1 is required for 1 <= i <= ndims(A).
vector(A)	Returns a 1-vector, if A is a scalar and otherwise returns a vector containing all the elements of the array, provided there is at most one dimension size > 1.
matrix(A)	Returns promote(A,2), if A is a scalar or vector and otherwise returns the elements of the first two dimensions as a matrix. size(A,i) = 1 is required for 2 < i <= ndims(A).
transpose(A)	Permutates the first two dimensions of array A. It is an error, if array A does not have at least 2 dimensions.
outerProduct(v1,v2)	Returns the outer product of vectors v1 and v2 (= matrix(v)*transpose(matrix(v))).
identity(n)	Returns the n x n Integer identity matrix, with ones on the diagonal and zeros at the other places.
diagonal(v)	Returns a square matrix with the elements of vector v on the diagonal and all other elements zero.
zeros(n1,n2,n3,...)	Returns the n ₁ x n ₂ x n ₃ x ... Integer array with all elements equal to zero (n _i >= 0).
ones(n1,n2,n3,...)	Return the n ₁ x n ₂ x n ₃ x ... Integer array with all elements equal to one (n _i >= 0).
fill(s,n1,n2,n3, ...)	Returns the n ₁ x n ₂ x n ₃ x ... array with all elements equal to scalar expression s which has to be a subtype of Real, Integer, Boolean or String (n _i >= 0). The returned array has the same type as s.
linspace(x1,x2,n)	Returns a Real vector with n equally spaced elements, such that v=linspace(x1,x2,n), v[i] = x1 + (x2-x1)*(i-1)/(n-1) for 1 <= i <= n. It is required that n >= 2. The arguments x1 and x2 shall be numeric scalar expressions.
min(A)	Returns the smallest element of array expression A.
min(x,y)	Returns the smallest element of the scalars x and y.
min(e(i, ..., j) for i in	Described in section 3.4.3.1.

u, ..., j in v	Returns the smallest value of the scalar expression $e(i, \dots, j)$ evaluated for all combinations of i in u, \dots, j in v :
max(A)	Returns the largest element of array expression A .
max(x,y)	Returns the largest element of the scalars x and y .
max(e(i, ..., j) for i in u, ..., j in v)	Described in section 3.4.3.1. Returns the largest value of the scalar expression $e(i, \dots, j)$ evaluated for all combinations of i in u, \dots, j in v :
sum(A)	Returns the scalar sum of all the elements of array expression: $A[1,\dots,1]+A[2,\dots,1]+\dots+A[\text{end},\dots,1]+A[\text{end},\dots,\text{end}]$
sum(e(i, ..., j) for i in u, ..., j in v)	Described in section 3.4.3.1. Returns the sum of the expression $e(i, \dots, j)$ evaluated for all combinations of i in u, \dots, j in v : $e(u[1],\dots,v[1])+e(u[2],\dots,v[1])+\dots+e(u[\text{end}],\dots,v[1])+\dots+e(u[\text{end}],\dots,v[\text{end}])$ The type of sum(e(i, ..., j) for i in u, ..., j in v) is the same as the type of $e(i,\dots,j)$.
product(A)	Returns the scalar product of all the elements of array expression A . $A[1,\dots,1]*A[2,\dots,1]*\dots*A[\text{end},\dots,1]*A[\text{end},\dots,\text{end}]$
product(e(i, ..., j) for i in u, ..., j in v)	Described in section 3.4.3.1. Returns the product of the scalar expression $e(i, \dots, j)$ evaluated for all combinations of i in u, \dots, j in v : $e(u[1],\dots,v[1])*e(u[2],\dots,v[1])*\dots*(u[\text{end}],\dots,v[1])*\dots*e(u[\text{end}],\dots,v[\text{end}])$ The type of product(e(i, ..., j) for i in u, ..., j in v) is the same as $e(i,\dots,j)$.
symmetric(A)	Returns a matrix where the diagonal elements and the elements above the diagonal are identical to the corresponding elements of matrix A and where the elements below the diagonal are set equal to the elements above the diagonal of A , i.e., $B := \text{symmetric}(A) \rightarrow B[i,j] := A[i,j]$, if $i \leq j$, $B[i,j] := A[j,i]$, if $i > j$.
cross(x,y)	Returns the cross product of the 3-vectors x and y , i.e. $\text{cross}(x,y) = \text{vector}([x[2]*y[3]-x[3]*y[2]; x[3]*y[1]-x[1]*y[3]; x[1]*y[2]-x[2]*y[1]])$;
skew(x)	Returns the 3 x 3 skew symmetric matrix associated with a 3-vector, i.e., $\text{cross}(x,y) = \text{skew}(x)*y$; $\text{skew}(x) = [0, -x[3], x[2]; x[3], 0, -x[1]; -x[2], x[1], 0]$;

[Example:

```

Real x[4, 1, 6];
size(x, 1) = 4;
size(x);           // vector with elements 4, 1, 6
size(2*x+x) = size(x);

Real[3] v1 = fill(1.0, 3);
Real[3, 1] m = matrix(v1);
Real[3] v2 = vector(m);

Boolean check[3, 4] = fill(true, 3, 4);
    
```

]

3.4.3.1 Reduction expressions

An expression

```
function-name "(" expression1 for iterators ")"
```

is a reduction-expression. The expressions in the iterators of a reduction-expression shall be vector expressions. They are evaluated once for each reduction-expression, and are evaluated in the scope immediately enclosing the reduction-expression.

For an iterator

```
IDENT in expression2
```

the loop-variable, IDENT, is in scope inside expression1. The loop-variable may hide other variables, as in for-clauses. The result depends on the function-name, and currently the only legal function-names are the built-in operators array, sum, product, min, and max. For array, see section 3.4.4.2. If function-name is sum, product, min, or max the result is of the same type as expression1 and is constructed by evaluating expression1 for each value of the loop-variable and computing the sum, product, min, or max of the computed elements. For deduction of ranges, see section 3.3.3.1.

Function-name	Restriction on expression1	Result if expression2 is empty
sum	None	zeros(...)
product	Scalar	1
min	Scalar	Modelica.Constants.inf
max	Scalar	-Modelica.Constants.inf

[Example:

```
sum(i for i in 1:10)           // Gives  $\sum_{i=1}^{10} i = 1+2+\dots+10=55$ 
// Read it as: compute the sum of i for i in the range 1 to 10.
sum(i^2 for i in {1,3,7,6}) // Gives  $\sum_{i \in \{1, 3, 7, 6\}} i^2 = 1+9+49+36=95$ 
{product(j for j in 1:i) for i in 0:4} // Gives {1,1,2,6,24}
max(i^2 for i in {3,7,6})     // Gives 49
```

]

3.4.4 Vector, Matrix and Array Constructors

3.4.4.1 Array Construction

The constructor function **array**(A,B,C,...) constructs an array from its arguments according to the following rules:

- Size matching: All arguments must have the same sizes, i.e., $\text{size}(A) = \text{size}(B) = \text{size}(C) = \dots$
- All arguments must be *type equivalent*. The datatype of the result array is the maximally expanded type of

the arguments. The maximally expanded types should be equivalent. Real and Integer subtypes can be mixed resulting in a Real result array where the Integer numbers have been transformed to Real numbers.

- Each application of this constructor function adds a one-sized dimension to the left in the result compared to the dimensions of the argument arrays, i.e., $\text{ndims}(\text{array}(A,B,C)) = \text{ndims}(A) + 1 = \text{ndims}(B) + 1, \dots$
- $\{A, B, C, \dots\}$ is a shorthand notation for $\text{array}(A, B, C, \dots)$.
- There must be at least one argument [*i.e.*, $\text{array}()$ or $\{\}$ is not defined].

[Examples:

```
{1,2,3} is a 3 vector of type Integer.
{{11,12,13}, {21,22,23}} is a 2x3 matrix of type Integer
{{{1.0, 2.0, 3.0}}} is a 1x1x3 array of type Real.

Real[3] v = array(1, 2, 3.0);
type Angle = Real(unit="rad");
parameter Angle alpha = 2.0; // type of alpha is Real.
// array(alpha, 2, 3.0) is a 3 vector of type Real.
Angle[3] a = {1.0, alpha, 4}; // type of a is Real[3].
```

]

3.4.4.2 Array constructor with iterators

An expression

```
"{" expression for iterators "}"
or
array "(" expression for iterators ")"
```

is an array constructor with iterators. The expressions inside the iterators of an array constructor shall be vector expressions. They are evaluated once for each array constructor, and is evaluated in the scope immediately enclosing the array constructor.

For an iterator

```
IDENT in array_expression
```

the loop-variable, IDENT, is in scope inside expression in the array construction. The loop-variable may hide other variables, as in for-clauses. For deduction of ranges, see section 3.3.3.1.

Array constructor with one iterator

If only one iterator is used, the result is a vector constructed by evaluating expression for each value of the loop-variable and forming an array of the result.

[Example:

```
array(i for i in 1:10)
// Gives the vector 1:10={1,2,3,...,10}

{r for r in 1.0 : 1.5 : 5.5}
// Gives the vector 1.0:1.5:5.5={1.0, 2.5, 4.0, 5.5}
```

```

i^2 for i in {1,3,7,6}
// Gives the vector {1, 9, 49, 36}

```

Array constructor with several iterators

The notation with several iterators is a shorthand notation for nested array constructors. The notation can be expanded into the usual form by replacing each ',' by '}' for ' and prepending the array constructor with a '{'.

[Example:

```

Real hilb[:, :]= {(1/(i+j-1) for i in 1:n, j in 1:n};
Real hilb2[:, :]= {(1/(i+j-1) for j in 1:n} for i in 1:n}

```

3.4.4.3 Array Concatenation

The function `cat(k,A,B,C,...)` concatenates arrays A,B,C,... along dimension k according to the following rules:

- Arrays A, B, C, ... must have the same number of dimensions, i.e., $\text{ndims}(A) = \text{ndims}(B) = \dots$
- Arrays A, B, C, ... must be *type equivalent*. The datatype of the result array is the maximally expanded type of the arguments. The maximally expanded types should be equivalent. Real and Integer subtypes can be mixed resulting in a Real result array where the Integer numbers have been transformed to Real numbers.
- k has to characterize an existing dimension, i.e., $1 \leq k \leq \text{ndims}(A) = \text{ndims}(B) = \text{ndims}(C)$; k shall be an integer number.
- Size matching: Arrays A, B, C, ... must have identical array sizes with the exception of the size of dimension k, i.e., $\text{size}(A,j) = \text{size}(B,j)$, for $1 \leq j \leq \text{ndims}(A)$ and $j \neq k$.

[Examples:

```

Real[2,3] r1 = cat(1, {{1.0, 2.0, 3}}, {{4, 5, 6}});
Real[2,6] r2 = cat(2, r1, 2*r1);

```

]

Concatenation is formally defined according to:

Let $R = \text{cat}(k,A,B,C,\dots)$, and let $n = \text{ndims}(A) = \text{ndims}(B) = \text{ndims}(C) = \dots$, then

$\text{size}(R,k) = \text{size}(A,k) + \text{size}(B,k) + \text{size}(C,k) + \dots$

$\text{size}(R,j) = \text{size}(A,j) = \text{size}(B,j) = \text{size}(C,j) = \dots$, for $1 \leq j \leq n$ and $j \neq k$.

$R[i_1, \dots, i_k, \dots, i_n] = A[i_1, \dots, i_k, \dots, i_n]$, for $i_k \leq \text{size}(A,k)$,

$R[i_1, \dots, i_k, \dots, i_n] = B[i_1, \dots, i_k - \text{size}(A,k), \dots, i_n]$, for $i_k \leq \text{size}(A,k) + \text{size}(B,k)$,

....

where $1 \leq i_j \leq \text{size}(R,j)$ for $1 \leq j \leq n$.

3.4.4.4 Array Concatenation along First and Second Dimensions

For convenience, a special syntax is supported for the concatenation along the first and second dimensions.

- *Concatenation along first dimension:*
 $[A; B; C; \dots] = \text{cat}(1, \text{promote}(A,n), \text{promote}(B,n), \text{promote}(C,n), \dots)$ where $n = \max(2, \text{ndims}(A), \text{ndims}(B), \text{ndims}(C), \dots)$. If necessary, 1-sized dimensions are added to the right of A, B, C before the operation is carried out, in order that the operands have the same number of dimensions which will be at least two.

- *Concatenation along second dimension:*
 $[A, B, C, \dots] = \text{cat}(2, \text{promote}(A,n), \text{promote}(B,n), \text{promote}(C,n), \dots)$ where
 $n = \max(2, \text{ndims}(A), \text{ndims}(B), \text{ndims}(C), \dots)$. If necessary, 1-sized dimensions are added to the right of A, B, C before the operation is carried out, especially that each operand has at least two dimensions.
- The two forms can be mixed. $[\dots\dots]$ has higher precedence than $[\dots;\dots]$, e.g., $[a, b; c, d]$ is parsed as $[[a,b]; [c,d]]$.
- $[A] = \text{promote}(A, \max(2, \text{ndims}(A)))$, i.e., $[A] = A$, if A has 2 or more dimensions, and it is a matrix with the elements of A, if A is a scalar or a vector.
- There must be at least one argument (i.e. $[]$ is not defined)

[Examples:

```
Real s1, s2, v1[n1], v2[n2], M1[m1,n],
    M2[m2,n], M3[n,m1], M4[n,m2], K1[m1,n,k], K2[m2,n,k];
```

[v1;v2] is a (n1+n2) x 1 matrix

[M1;M2] is a (m1+m2) x n matrix

[M3,M4] is a n x (m1+m2) matrix

[K1;K2] is a (m1+m2) x n x k array

[s1;s2] is a 2 x 1 matrix

[s1,s1] is a 1 x 2 matrix

[s1] is a 1 x 1 matrix

[v1] is a n1 x 1 matrix

```
Real[3] v1 = array(1, 2, 3);
Real[3] v2 = {4, 5, 6};
Real[3,2] m1 = [v1, v2];
Real[3,2] m2 = [v1, [4;5;6]]; // m1 = m2
Real[2,3] m3 = [1, 2, 3; 4, 5, 6];
Real[1,3] m4 = [1, 2, 3];
Real[3,1] m5 = [1; 2; 3];
```

]

3.4.4.5 Vector Construction

Vectors can be constructed with the general array constructor, e.g., $\text{Real}[3] \ v = \{1, 2, 3\}$.

The colon operator of *simple-expression* can be used instead of or in combination with this general constructor to construct Real and Integer vectors. Semantics of the colon operator:

- $j : k$ is the Integer vector $\{j, j+1, \dots, k\}$, if j and k are of type Integer.
- $j : k$ is the Real vector $\{j, j+1.0, \dots, n\}$, with $n = \text{floor}(k-j)$, if j and/or k are of type Real.
- $j : k$ is a Real or Integer vector with zero elements, if $j > k$.
- $j : d : k$ is the Integer vector $\{j, j+d, \dots, j+n*d\}$, with $n = (k-j)/d$, if j , d , and k are of type Integer.
- $j : d : k$ is the Real vector $\{j, j+d, \dots, j+n*d\}$, with $n = \text{floor}((k-j)/d)$, if j , d , or k are of type Real.
- $j : d : k$ is a Real or Integer vector with zero elements, if $d > 0$ and $j > k$ or if $d < 0$ and $j < k$.

[Examples:

```
Real v1[5] = 2.7 : 6.8;
```

```

    Real v2[5] = {2.7, 3.7, 4.7, 5.7, 6.7}; // = same as v1
]

```

3.4.5 Array access operator

Elements of vector, matrix or array variables are accessed with `[]`. A colon is used to denote all indices of one dimension. A vector expression can be used to pick out selected rows, columns and elements of vectors, matrices, and arrays. The number of dimensions of the expression is reduced by the number of scalar index arguments. The expression **end** may only appear inside array subscripts, and if used in the *i*:th subscript of an expression *A* it is equivalent to `size(A,i)`. If used inside nested array subscripts it refers to the most closely nested array.

It is also possible to use the array access operator to assign to element/elements of an array in algorithm sections. If the index is an array the assignments take place in the order given by the index array. For assignments to arrays and elements of arrays, the entire right-hand side and the index on the left-hand side is evaluated before any element is assigned a new value.

[Examples:

- `a[:, j]` is a vector of the *j*-th column of *a*,
- `a[j : k]` is $\{a[j], a[j+1], \dots, a[k]\}$
- `a[:, j : k]` is $[a[:,j], a[:,j+1], \dots, a[:,k]]$,
- `v[2:2:8] = v[{2,4,6,8}]` .
- `v[{j,k}] := {2,3};` // Same as `v[j] := 2; v[k] := 3;`
- `v[{1,1}] := {2,3};` // Same as `v[1] := 3;`
- `A[end-1,end]` is `A[size(A,1)-1,size(A,2)]`
- `A[v[end],end]` is `A[v[size(v,1)],size(A,2)]` // since the first end is referring to end of *v*.
- if *x* is a vector, `x[1]` is a scalar, but the slice `x[1 : 5]` is a vector (a vector-valued or colon index expression causes a vector to be returned).]

[Examples given the declaration `x[n, m], v[k], z[i, j, p]`:

Expression	# dimensions	Type of value
<code>x[1, 1]</code>	0	Scalar
<code>x[:, 1]</code>	1	<i>n</i> – Vector
<code>x[1, :]</code>	1	<i>m</i> – Vector
<code>v[1:p]</code>	1	<i>p</i> – Vector
<code>x[1:p, :]</code>	2	<i>p</i> x <i>m</i> – Matrix
<code>x[1:1, :]</code>	2	1 x <i>m</i> – "row" matrix
<code>x[{1, 3, 5}, :]</code>	2	3 x <i>m</i> – Matrix
<code>x[:, v]</code>	2	<i>n</i> x <i>k</i> – Matrix

$z[:, 3, :]$	2	$i \times p$ – Matrix
$x[\text{scalar}([1]), :]$	1	m – Vector
$x[\text{vector}([1]), :]$	2	$1 \times m$ - "row" matrix

]

3.4.6 Scalar, vector, matrix, and array operator functions

The mathematical operations defined on scalars, vectors, and matrices are the subject of linear algebra.

In all contexts that require an expression which is a subtype of Real, an expression which is a subtype of Integer can also be used; the Integer expression is automatically converted to Real.

The term *numeric class* is used below for a subtype of the Real or Integer type class.

3.4.6.1 Equality and Assignment of type classes

Equality “ $a=b$ ” and assignment “ $a:=b$ ” of scalars, vectors, matrices, and arrays is defined element-wise and require both objects to have the same number of dimensions and corresponding dimension sizes. The operands need to be type equivalent. This is legal for the simple types and all types satisfying the requirements for a record, and is in the latter case applied to each component-element of the records.

Type of a	Type of b	Result of $a = b$	Operation ($j=1:n, k=1:m$)
Scalar	Scalar	Scalar	$a = b$
Vector[n]	Vector[n]	Vector[n]	$a[j] = b[j]$
Matrix[n, m]	Matrix[n, m]	Matrix[n, m]	$a[j, k] = b[j, k]$
Array[n, m, ...]	Array[n, m, ...]	Array[n, m, ...]	$a[j, k, ...] = b[j, k, ...]$

3.4.6.2 Addition and Subtraction of numeric type classes and concatenation of strings

Addition “ $a+b$ ” and subtraction “ $a-b$ ” of numeric scalars, vectors, matrices, and arrays is defined element-wise and require $\text{size}(a) = \text{size}(b)$ and a numeric type class for a and b. Addition “ $a+b$ ” of string scalars, vectors, matrices, and arrays is defined as element-wise string concatenation of corresponding elements from a and b, and require $\text{size}(a) = \text{size}(b)$.

Type of a	Type of b	Result of $a +/- b$	Operation $c := a +/- b$ ($j=1:n, k=1:m$)
Scalar	Scalar	Scalar	$c := a +/- b$
Vector[n]	Vector[n]	Vector[n]	$c[j] := a[j] +/- b[j]$
Matrix[n, m]	Matrix[n, m]	Matrix[n, m]	$c[j, k] := a[j, k] +/- b[j, k]$
Array[n, m, ...]	Array[n, m, ...]	Array[n, m, ...]	$c [j, k, ...] := a[j, k, ...] +/- b[j, k, ...]$

3.4.6.3 Scalar Multiplication of numeric type classes

Scalar multiplication “ $s*a$ ” or “ $a*s$ ” with numeric scalar s and numeric scalar, vector, matrix or array a is defined element-wise:

Type of s	Type of a	Type of $s* a$ and $a*s$	Operation $c := s*a$ or $c := a*s$ ($j=1:n, k=1:m$)
-----------	-----------	--------------------------	---

Scalar	Scalar	Scalar	$c := s * a$
Scalar	Vector [n]	Vector [n]	$c[j] := s * a[j]$
Scalar	Matrix [n, m]	Matrix [n, m]	$c[j, k] := s * a[j, k]$
Scalar	Array[n, m, ...]	Array [n, m, ...]	$c[j, k, ...] := s * a[j, k, ...]$

3.4.6.4 Matrix Multiplication of numeric type classes

Multiplication “a*b” of numeric vectors and matrices is defined only for the following combinations:

Type of a	Type of b	Type of a * b	Operation $c := a * b$
Vector [n]	Vector [n]	Scalar	$c := \sum_k(a[k] * b[k]), k=1:n$
Vector [n]	Matrix [n, m]	Vector [m]	$c[j] := \sum_k(a[k] * b[k, j]), j=1:m, k=1:n$
Matrix [n, m]	Vector [m]	Vector [n]	$c[j] := \sum_k(a[j, k] * b[k])$
Matrix [n, m]	Matrix [m, p]	Matrix [n, p]	$c[i, j] = \sum_k(a[i, k] * b[k, j]), i=1:n, k=1:m, j=1:p$

[Example:

```

Real A[3,3], x[3], b[3], v[3];
A*x = b;
x*A = b; // same as transpose([x])*A*b
[v]*transpose([v]) // outer product
v*A*v // scalar
tranpose([v])*A*v // vector with one element

```

]

3.4.6.5 Scalar Division of numeric type classes

Division “a/s” of numeric scalars, vectors, matrices, or arrays a and numeric scalars s is defined element-wise. The result is always of real type. In order to get integer division with truncation use the function **div**.

Type of a	Type of s	Result of a / s	Operation $c := a / s (j=1:n, k=1:m)$
Scalar	Scalar	Scalar	$c := a / s$
Vector[n]	Scalar	Vector[n]	$c[k] := a[k] / s$
Matrix[n, m]	Scalar	Matrix[n, m]	$c[j, k] := a[j, k] / s$
Array[n, m, ...]	Scalar	Array[n, m, ...]	$c[j, k, ...] := a[j, k, ...] / s$

3.4.6.6 Exponentiation of Scalars of numeric type classes

Exponentiation “a^b” is defined as `pow()` in the C language if both “a” and “b” are scalars of a numeric type class.

3.4.6.7 Scalar Exponentiation of Square Matrices of numeric type classes

Exponentiation “a^s” is defined if “a” is a square numeric matrix and “s” is a scalar as a subtype of Integer with

$s \geq 0$. The exponentiation is done by repeated multiplication
(e.g. $a^3 = a*a*a$; $a^0 = \text{identity}(\text{size}(a,1))$; $\text{assert}(\text{size}(a,1)=\text{size}(a,2), \text{"Matrix must be square"})$; $a^1 = a$).

[Non-Integer exponents are forbidden, because this would require to compute the eigenvalues and eigenvectors of "a" and this is no longer an elementary operation].

3.4.6.8 Slice operation

If a is an array containing scalar components and m is a component of those components, the expression $a.m$ is interpreted as a *slice operation*. It returns the array of components $\{a[1].m, \dots\}$.

If m is also an array component, the slice operation is valid only if $\text{size}(a[1].m)=\text{size}(a[2].m)=\dots$

3.4.6.9 Relational operators

Relational operators $<$, $<=$, $>$, $>=$, $=$, $<>$, are only defined for *scalar* operands of simple types. The result is Boolean and is **true** or **false** if the relation is fulfilled or not, respectively.

For operands of type String, $\text{str1 } op \text{ str2}$ is for each relational operator, op , defined in terms of the C-function strcmp as $\text{strcmp}(\text{str1}, \text{str2}) \text{ } op \text{ } 0$.

For operands of type Boolean, $\text{false} < \text{true}$.

For operands of enumeration types, the order is given by the order of declaration of the enumeration literals.

In relations of the form $v1 = v2$ or $v1 <> v2$, $v1$ or $v2$ shall not be a subtype of Real. *[The reason for this rule is that relations with Real arguments are transformed to state events (see section Events below) and this transformation becomes unnecessarily complicated for the $=$ and $<>$ relational operators (e.g. two crossing functions instead of one crossing function needed, epsilon strategy needed even at event instants). Furthermore, testing on equality of Real variables is questionable on machines where the number length in registers is different to number length in main memory].*

Relations of the form " $v1 \text{ rel_op } v2$ ", with $v1$ and $v2$ variables and rel_op a relational operator are called elementary relations. If either $v1$ or $v2$ or both variables are a subtype of Real, the relation is called a Real elementary relation.

3.4.6.10 Boolean operators

The operators, "and" and "or" take expressions of boolean type, which are either scalars or arrays of matching dimensions. The operator "not" takes an expression of boolean type, which is either scalar or an array. The result is the element-wise logical operation. For short-circuit evaluation of "and" and "or" see section 3.4.1.

3.4.6.11 Vectorized call of functions

Functions with one scalar return value can be applied to arrays element-wise, e.g. if A is a vector of reals, then $\sin(A)$ is a vector where each element is the result of applying the function \sin to the corresponding element in A .

Consider the expression $f(\text{arg1}, \dots, \text{argn})$, an application of the function f to the arguments $\text{arg1}, \dots, \text{argn}$ is defined.

For each passed argument, the type of the argument is checked against the type of the corresponding formal parameter of the function.

1. If the types match, nothing is done.
2. If the types do not match, and a type conversion can be applied, it is applied. Continued with step 1.

3. If the types do not match, and no type conversion is applicable, the passed argument type is checked to see if it is an n-dimensional array of the formal parameter type. If it is not, the function call is invalid. If it is, we call this a foreach argument.
4. For all foreach arguments, the number and sizes of dimensions must match. If they do not match, the function call is invalid. If no foreach argument exists, the function is applied in the normal fashion, and the result has the type specified by the function definition.
5. The result of the function call expression is an n-dimensional array with the same dimension sizes as the foreach arguments. Each element $e_{i,\dots,j}$ is the result of applying f to arguments constructed from the original arguments in the following way.
 - If the argument is not a foreach argument, it is used as-is.
 - If the argument is a foreach argument, the element at index $[i,\dots,j]$ is used.

If more than one argument is an array, all of them have to be the same size, and they are traversed in parallel.

[Examples:

```

sin({a, b, c})           = {sin(a), sin(b), sin(c)} // argument is a vector
sin([a,b,c])           = [sin(a), sin(b), sin(c)] // argument may be a matrix
atan({a,b,c},{d,e,f}) = {atan(a,d), atan(b,e), atan(c,f)}

```

This works even if the function is declared to take an array as one of its arguments. If pval is defined as a function that takes one argument that is a vector of Reals and returns a Real, then it can be used with an actual argument which is a two-dimensional array (a vector of vectors). The result type in this case will be a vector of Real.

```

pval([1,2;3,4]) = [pval([1,2]); pval([3,4])]
sin([1,2;3,4]) = [sin({1,2}); sin({3,4})]
               = [sin(1), sin(2); sin(3), sin(4)]

```

```

function Add
  input Real e1, e2;
  output Real sum1;
  algorithm
    sum1 := e1 + e2;
end Add;

```

Add(1, [1, 2, 3]) adds one to each of the elements of the second argument giving the result [2, 3, 4]. However, it is illegal to write $1 + [1, 2, 3]$, because the rules for the built-in operators are more restrictive.]

3.4.6.12 Empty Arrays

Arrays may have dimension sizes of 0. E.g.

```

Real x[0]; // an empty vector
Real A[0, 3], B[5, 0], C[0, 0]; // empty matrices

```

- Empty matrices can be constructed with the fill function. E.g.

```

Real A[:,:] = fill(0.0, 0, 1); // a Real 0 x 1 matrix
Boolean B[:, :] = fill(false, 0, 1, 0); // a Boolean 0 x 1 x 0 matrix

```
- It is not possible to access an element of an empty matrix, e.g. $v[j,k]$ is wrong if “ $v=[]$ ” because the assertion fails that the index must be bigger than one.

- Size-requirements of operations, such as +, -, have also to be fulfilled if a dimension is zero. E.g.

```
Real[3,0] A, B;
Real[0,0] C;
A + B // fine, result is an empty matrix
A + C // error, sizes do not agree
```
- Multiplication of two empty matrices results in a zero matrix if the result matrix has no zero dimension sizes, i.e.,

```
Real[0,m]*Real[m,n] = Real[0,n] (empty matrix)
Real[m,n]*Real[n,0] = Real[m,0] (empty matrix)
Real[m,0]*Real[0,n] = zeros(m,n) (non-empty matrix, with zero elements).
```

[Example:

```
Real u[p], x[n], y[q], A[n,n], B[n,p], C[q,n], D[q,p];
der(x) = A*x + B*u
y = C*x + D*u
```

Assume $n=0, p>0, q>0$: Results in "y = D*u"

]

3.4.7 If-expression

An expression

```
if expression1 then expression2 else expression3
```

is one example of if-expression. First expression1, which must be boolean expression, is evaluated. If expression1 is true expression2 is evaluated and is the value of the if-expression, else expression3 is evaluated and is the value of the if-expression. The two expressions, expression2 and expression3, must be type compatible and give the type of the if-expression. If-expressions with **elseif** are defined by replacing **elseif** by **else if**. [Note: *elseif* is added for symmetry with *if*-clauses.] For short-circuit evaluation see section 3.4.1.

[Example:

```
Integer i;
Integer sign_of_i1=if i<0 then -1 elseif i==0 then 0 else 1;
Integer sign_of_i2=if i<0 then -1 else if i==0 then 0 else 1;
```

]

Functions

Function classes and record constructors can be called as described in this section. It also possible to declare components of function type, see section 3.2.13.

3.4.8.1 Formal input parameters of functions

A function application, see section 2.2.7, has optional positional arguments followed by zero, one or more named arguments, such as

```
f(3.5, 5.76, arg3=5, arg6=8.3);
```

The interpretation of a function application is as follows: First, a list of unfilled slots is created for all formal input parameters. If there are N positional arguments, they are placed in the first N slots, where the order of the parameters is given by the order of the component declarations in the function definition. Next, for each named

argument "identifier = expression", the identifier is used to determine the corresponding slot. This slot shall be not filled [*otherwise an error occurs*] and the value of the argument is placed in the slot, filling it. When all arguments have been processed, the slots that are still unfilled are filled with the corresponding default value of the function definition. There shall be no remaining unfilled slots [*otherwise an error occurs*] and the list of filled slots is used as the argument list for the call.

The type of each argument must agree with the type of the corresponding parameter, except where the standard type coercions can be used to make the types agree. (See also section 3.4.6.10 on applying scalar functions to arrays.)

[*Example.*

Suppose a function *RealToString* is defined as follows to convert a Real number to a String:

```
function RealToString
  input Real number;
  input Real precision = 6 "number of significantdigits";
  input Real length    = 0 "minimum length of field";
  output String string "number as string";
  ...
end RealToString;
```

Then the following applications are equivalent:

```
RealToString(2.0);
RealToString(2.0, 6, 0);
RealToString(2.0, 6);
RealToString(2.0, precision=6);
RealToString(2.0, length=0);
RealToString(2.0, 6, precision=6); // error: slot is used twice
```

]

3.4.8.2 Formal output parameters of functions

A function may have more than one output component, corresponding to multiple return values. The only way to call a function returning more than one result is to make the function call the right hand side of an equation or assignment. In these cases, the left hand side of the equation or assignment shall contain a list of component references within parentheses:

```
(out1, out2, out3) = f(...);
```

The component references are associated with the output components according to their position in the list. Thus output component *i* is set equal to, or assigned to, component reference *i* in the list, where the order of the output components is given by the order of the component declarations in the function definition. The type of each component reference in the list must agree with the type of the corresponding output component.

A function application may be used as expression whose value and type is given by the value and type of the first output component, if exactly one return result is provided.

It is possible to have optional results from a function. An output result is provided, if the "enable" attribute of the corresponding output component is **true**, and is otherwise not provided. If an output result is provided, a corresponding component reference shall be present to receive the result, otherwise it shall not be present. If an output component has enable = **false**, all subsequent output components shall also have enable = **false**.

[*A Modelica translator may check the above restrictions with the enable attribute during translation, if the*

assignment "enable = BooleanExpression" can be evaluated at translation time.

Example:

Function "eigen" to compute eigenvalues and optionally eigenvectors may be called in the following ways:

```

    ev = eigen(A); // calculate eigenvalues
    x = isStable(eigen(A)); // used in an expression
    (ev, vr) = eigen(A, getRightVec=true) // calculate eigenvectors
    (ev, vr) = eigen(A, getRightVec=false) // error, vr provided,
    // although enable = false
    (,vr) = eigen(A, getRightVec=true) // syntax error,
    // argument missing
    (ev,vr,vl) = eigen(A, getLeftVec =true) // error, enable=false for
    // argument 2 and enable = true
    // for argument 3

```

The function may be defined as:

```

function eigen "calculate eigenvalues and optionally eigenvectors"
  parameter Integer n = size(A,1);
  input Real A[:, size(A,1)];
  input Boolean getRightVec = false;
  input Boolean getLeftVec = false;
  output Real eigenValues[n,2];
  output Real rightEigenVectors[n,n] (enable = getRightVec);
  output Real leftEigenVectors [n,n] (enable = getLeftVec);
algorithm
  // compute eigenvalues
  if getRightVec then
    // compute right eigenvectors
  end if;
  if getLeftVec then
    // compute left eigenvectors
  end if;
end eigen;

```

]

The only permissible use of an expression in the form of a list of expressions in parentheses, is when it is used as the left hand side of an equation or assignment where the right hand side is an application of a function.

[Example. The following are illegal:

```

    (x+1, 3.0, z/y) = f(1.0, 2.0); // Not a list of component references.
    (x, y, z) + (u, v, w) // Not LHS of suitable eqn/assignment.

```

]

3.4.8.3 Record constructor

Whenever a record is defined, a record constructor function with the same name and in the same scope as the record class is implicitly defined according to the following rules:

- The declaration of the record is partially instantiated including inheritance, modifications, redeclarations,

and expansion of all names referring to declarations outside of the scope of the record to their fully qualified names [in order to remove potentially conflicting import statements in the record constructor function due to flattening the inheritance tree].

- All record elements [i.e., components and local class definitions] of the partially instantiated record declaration are used as declarations in the record constructor function with the following exceptions: (1) Component declarations which do not allow a modification [such as "**constant** Real c=1" or "**final parameter** Real"] are declared as protected components in the record constructor function. (2) Prefixes (**constant**, **parameter**, **final**, **discrete**, **input**, **output**, ...) of the remaining record components are removed. (3) The prefix "**input**" is added to the **public** components of the record constructor function.
- An instance of the record is declared as output parameter [using a name, not appearing in the record] together with a modification. In the modification, all input parameters are used to set the corresponding record variables.

[This allows to construct an instance of a record, with an optional modification, at all places where a function call is allowed. Examples:

```

record Complex "Complex number"
  Real re "real part";
  Real im "imaginary part";
end Complex;

function add
  input Complex u, v;
  output Complex w(re=u.re + v.re, im=u.im+v.re);
end add;

Complex c1, c2;
equation
  c2 = add(c1, Complex(sin(time), cos(time)));

```

In the following example, a convenient data sheet library of components is built up:

```

package Motors
  record MotorData "Data sheet of a motor"
    parameter Real inertia;
    parameter Real nominalTorque;
    parameter Real maxTorque;
    parameter Real maxSpeed;
  end MotorData;

  model Motor "Motor model" // using the generic MotorData
    MotorData data;
    ...
  equation
    ...
  end Motor;

  record MotorI123 = MotorData( // data of a specific motor
    inertia      = 0.001,
    nominalTorque = 10,

```

```

    maxTorque      = 20,
    maxSpeed       = 3600) "Data sheet of motor I123";

    record MotorI145 = MotorData( // data of another specific motor
      inertia       = 0.0015,
      nominalTorque = 15,
      maxTorque     = 22,
      maxSpeed      = 3600) "Data sheet of motor I145";
end Motors

model Robot
  import Motors.*;
  Motor motor1(data = MotorI123()); // just refer to data sheet
  Motor motor2(data = MotorI123(inertia=0.0012));
    // data can still be modified (if no final declaration in record)
  Motor motor3(data = MotorI145());
  ...
end Robot;

```

Example showing most of the situations, which may occur for the implicit record constructor function creation. With the following record definitions

```

package Demo;
  record Record1;
    parameter Real r0 = 0;
  end Record1;

  record Record2
    import Modelica.Math.*;
    extends Record1;
    constant Real c1 = 2.0;
    constant Real c2;
    parameter Integer n1 = 5;
    parameter Integer n2;
    parameter Real r1 "comment";
    parameter Real r2 = sin(c1);
    final parameter Real r3 = cos(r2);
    Real r4;
    Real r5 = 5.0;
    Real r6[n1];
    Real r7[n2];

  end Record2;
end Demo;

```

the following record constructor functions are implicitly defined

```

package Demo;
  function Record1
    input Real r0 = 0;

```

```

    output Record1 'result' (r0 = r0);
end Record1;

function Record2
  input Real    r0 = 0;
  input Real    c2;
  input Integer n1 := 5;
  input Integer n2;
  input Real    r1 "comment"; // the comment also copied from record
  input Real    r2 := Modelica.Math.sin(c1);
  input Real    r4;
  input Real    r5 = 5.0;
  input Real    r6[n1];
  input Real    r7[n2];
  output Record2 'result' (r0=r0,c2=c2,n1=n1,n2=n2,r1=r1,r2=r2,
                          r4=r4,r5=r5,r6=r6,r7=r7);

  protected
    constant Real c1 = 2.0; // referenced from r2
    final parameter Real r3 = Modelica.Math.cos(r2);

  end Record2;
end Demo;

```

and can be applied in the following way

```

Demo.Record2 r1 = Demo.Record2(r0=1, c2=2, n1=2, n2=3, r1=1, r2=2,
                              r4=5, r5=5, r6={1,2}, r7={1,2,3});
Demo.Record2 r2 = Demo.Record2(1,2,2,3,1,2,5,5,{1,2},{1,2,3});
parameter Demo.Record2 r3 = Demo.Record2(c2=2, n2=1, r1=1, r4=4,
                                          r6=1:5, r7={1});

```

The above example is only used to show the different variants appearing with prefixes, but it is not very meaningful, because it is simpler to just use a direct modifier.

]

3.4.9 Variability of Expressions

Constant expressions are:

- Real, Integer, Boolean and String literals.
- Real, Integer, Boolean and String variables declared as **constant** .
- Except for the special built-in operators **initial**, **terminal**, **der**, **edge**, **change**, **sample**, **pre** and **analysisType** a function or operator with constant subexpressions as argument (and no parameters defined in the function) is a constant expression.

Parameter expressions are:

- Constant expressions.

- Real, Integer, Boolean and String variables declared as **parameter**.
- Except for the special built-in operators **initial**, **terminal**, **der**, **edge**, **change**, **sample** and **pre** a function or operator with parameter subexpressions is a parameter expression.
- The function **analysisType()** is parameter expression.

Discrete-time expressions are:

- Parameter expressions.
- Discrete-time variables, i.e. Integer, Boolean and String variables, as well as Real variables assigned in when-clauses
- Function calls where all input arguments of the function are **discrete-time** expressions.
- Expressions where all the subexpressions are **discrete-time** expressions.
- Expressions in the body of a **when** clause.
- Unless inside **noEvent**: Ordered relations ($>$, $<$, $>=$, $<=$) and the functions **ceil**, **floor**, **div**, **mod**, **rem**, **abs**, **sign**. These will generate events if they have continuous-time subexpressions. *[In other words, relations inside **noEvent()**, such as **noEvent**($x > 1$), are continuous-time expressions].*
- The functions **pre**, **edge**, and **change** result in discrete-time expressions.
- Expressions in functions behave as though they were **discrete-time** expressions.

Components declared as **constant** shall have an associated declaration equation with a constant expression, if the constant is used in the model. The value of a constant cannot be changed after it has been given a value. A constant without an associated declaration equation can be given one by using a modifier.

For an assignment $v := \text{expr}$ or declaration equation $v = \text{expr}$, v must be declared to be at least as variable as expr .

- The declaration equation of a **parameter** component and of the base type attributes *[such as start]* needs to be a parameter expression.
- If v is a discrete-time component then expr needs to be a discrete-time expression.

For an equation $\text{expr1} = \text{expr2}$ where neither expression is of base type Real, both expressions must be discrete-time expressions. For record equations the equation is split into basic types before applying this test. *[This restriction guarantees that the **noEvent()** operator cannot be applied to Boolean, Integer or String equations outside of a when-clause, because then one of the two expressions is not discrete-time]*

Inside an if-expression, if-clause or for-clause, that is controlled by a continuous-time switching expression and not in the body of a when-clause, it is not legal to have assignments to discrete variables, equations between discrete-time expressions, or real elementary relations/functions that should generate events. *[This restriction is necessary in order to guarantee that there are no continuous-time equations for discrete variables, and to ensure that crossing functions do not become active between events.]*

[Example:

```

model Constants
  parameter Real p1 = 1;
  constant Real c1 = p1 + 2; // error, no constant expression
  parameter Real p2 = p1 + 2; // fine
end Constants;

```

```

model Test
  Constants c1(p1=3); // fine
  Constants c2(p2=7); // fine, declaration equation can be modified
  Boolean b;
  Real x;
equation
  b = noEvent(x > 1) // error, since b is a discrete-time and
                    // noEvent(x > 1) is a continuous-time expression.
end Test;
]

```

3.5 Events and Synchronization

The integration is halted and an event occurs whenever a Real elementary relation, e.g. “ $x > 2$ ”, changes its value. The value of a relation can only be changed at event instants [*in other words, Real elementary relations induce state or time events*]. The relation which triggered an event changes its value when evaluated literally before the model is processed at the event instant [*in other words, a root finding mechanism is needed which determines a small time interval in which the relation changes its value; the event occurs at the **right** side of this interval*]. Relations in the body of a when-clause are always taken literally. During continuous integration a Real elementary relation has the *constant* value of the relation from the last event instant.

[*Example:*

```
y = if u > uMax then uMax else if u < uMin then uMin else u;
```

During continuous integration always the same if-branch is evaluated. The integration is halted whenever $u - u_{\text{Max}}$ or $u - u_{\text{Min}}$ crosses zero. At the event instant, the correct if-branch is selected and the integration is restarted.

Numerical integration methods of order n ($n \geq 1$) require continuous model equations which are differentiable upto order n . This requirement can be fulfilled if Real elementary relations are not treated literally but as defined above, because discontinuous changes can only occur at event instants and no longer during continuous integration.]

[*It is a quality of implementation issue that the following special relations*

```
time >= discrete expression
time < discrete expression
```

trigger a time event at “time = discrete expression”, i.e., the event instant is known in advance and no iteration is needed to find the exact event instant.]

Relations are taken literally also during continuous integration, if the relation or the expression in which the relation is present, are the argument of the **noEvent**(..) function. The **smooth**(p, x) operator also allows relations used as argument to be taken literally. The noEvent feature is propagated to all subrelations in the scope of the noEvent function. For smooth the liberty to not allow literal evaluation is propagated to all subrelations, but the smooth-property itself is not propagated.

[*Example:*

```

x = if noEvent(u > uMax) then uMax elseif noEvent(u < uMin) then uMin
    else u;
y = noEvent( if u > uMax then uMax elseif u < uMin then uMin else u);
z = smooth(0, if u > uMax then uMax elseif u < uMin then uMin else u);

```

In this case $x=y=z$, but a tool might generate events for z . The *if-expression* is taken literally without inducing state events.

The *smooth* function is useful, if e.g. the modeller can guarantee that the used *if-clauses* fulfill at least the continuity requirement of integrators. In this case the simulation speed is improved, since no state event iterations occur during integration. The *noEvent* function is used to guard against “outside domain” errors, e.g. $y = \text{if noEvent}(x \geq 0) \text{ then sqrt}(x) \text{ else } 0.$

All equations and assignment statements within *when clauses* and all assignment statements within *function classes* are implicitly treated with the *noEvent* function, i.e., relations within the scope of these operators never induce state or time events. [Using state events in *when-clauses* is unnecessary because the body of a *when clause* is not evaluated during continuous integration.]

[Example:

```

Limit1 = noEvent(x1 > 1);
// Error since Limit1 is a discrete-time variable

    when noEvent(x1>1) or x2>10 then
// error, when-conditions is not a discrete-time expression
    Close = true;
    end when;

```

Modelica is based on the synchronous data flow principle which is defined in the following way:

1. All variables keep their actual values until these values are explicitly changed. Variable values can be accessed at any time instant during continuous integration and at event instants.
2. At every time instant, during continuous integration and at event instants, the active equations express relations between variables which have to be fulfilled *concurrently* (equations are not active if the corresponding *if-branch*, *when-clause* or *block* in which the equation is present is not active).
3. Computation and communication at an event instant does not take time. [If computation or communication time has to be simulated, this property has to be explicitly modeled].
4. The total number of equations is identical to the total number of unknown variables (= single assignment rule).

[These rules guarantee that variables are always defined by a unique set of equations. It is not possible that a variable is e.g. defined by two equations, which would give rise to conflicts or non-deterministic behaviour. Furthermore, the continuous and the discrete parts of a model are always automatically “synchronized”.

Example:

```

equation // Illegal example
    when condition1 then
        close = true;
    end when;

    when condition2 then

```

```

    close = false;
  end when;

```

This is not a valid model because rule 4 is violated since there are two equations for the single unknown variable `close`. If this would be a valid model, a conflict occurs when both conditions become true at the same time instant, since no priorities between the two equations are assigned. To become valid, the model has to be changed to:

```

equation
  when condition1 then
    close = true;
  elsewhen condition2 then
    close = false;
  end when;

```

Here, it is well-defined if both conditions become true at the same time instant (condition1 has a higher priority than condition2).]

There is no guarantee that two different events occur at the same time instant.

[As a consequence, synchronization of events has to be explicitly programmed in the model, e.g. via counters. Example:

```

  Boolean fastSample, slowSample;
  Integer ticks(start=0);
equation
  fastSample = sample(0,1);
algorithm
  when fastSample then
    ticks      := if pre(ticks) < 5 then pre(ticks)+1 else 0;
    slowSample := pre(ticks) == 0;
  end when;
algorithm
  when fastSample then // fast sampling
    ...
  end when;
algorithm
  when slowSample then // slow sampling (5-times slower)
    ...
  end when;

```

The `slowSample` when-clause is evaluated at every 5th occurrence of the `fastSample` when clause.]

[The single assignment rule and the requirement to explicitly program the synchronization of events allow a certain degree of model verification already at compile time..]

Variable attributes of simple types

The attributes of the predefined variable types and enumeration types are described below with Modelica syntax although they are predefined; redeclaration of any of these types is an error. It is furthermore not possible to combine extends from the predefined types with other components. The definitions use `RealType`, `IntegerType`,

BooleanType, StringType, EnumType as mnemonics corresponding to machine representations. *[Hence the only way to declare a subtype of e.g. Real is to use the extends mechanism.]*

```

type Real
  RealType value; // Accessed without dot-notation
  parameter StringType quantity = "";
  parameter StringType unit = "" "Unit used in equations";
  parameter StringType displayUnit = "" "Default display unit";
  parameter RealType min=-Inf, max=+Inf; // Inf denotes a large value
  parameter RealType start = 0; // Initial value
  parameter BooleanType fixed = true, // default for parameter/constant;
    = false; // default for other variables
  parameter BooleanType enable = true; // defined for every class
  parameter RealType nominal; // Nominal value
  parameter StateSelect stateSelect = StateSelect.default;
equation
  assert(value >= min and value <= max, "Variable value out of limit");
  assert(nominal >= min and nominal <= max, "Nominal value out of limit");
end Real;

type Integer
  IntegerType value; // Accessed without dot-notation
  parameter StringType quantity = "";
  parameter IntegerType min=-Inf, max=+Inf;
  parameter IntegerType start = 0; // Initial value
  parameter BooleanType fixed = true, // default for parameter/constant;
    = false; // default for other variables
  parameter BooleanType enable = true; // defined for every class
equation
  assert(value >= min and value <= max, "Variable value out of limit");
end Integer;

type Boolean
  BooleanType value; // Accessed without dot-notation
  parameter StringType quantity = "";
  parameter BooleanType start = false; // Initial value
  parameter BooleanType fixed = true, // default for parameter/constant;
    = false, // default for other variables
  parameter BooleanType enable = true; // defined for every class
end Boolean;

type String
  StringType value; // Accessed without dot-notation
  parameter StringType quantity = "";
  parameter StringType start = ""; // Initial value
  parameter BooleanType enable = true; // defined for every class
end String;

type StateSelect = enumeration(
  never "Do not use as state at all.",
  avoid "Use as state, if it cannot be avoided (but only if variable appears

```

```

        differentiated and no other potential state with attribute
        default, prefer, or always can be selected).",
default "Use as state if appropriate, but only if variable appears
        differentiated.",
prefer "Prefer it as state over those having the default value
        (also variables can be selected, which do not appear
        differentiated). ",
always "Do use it as a state."
);

```

For each enumeration

```

    type E=enumeration(e1, e2, ..., en);
a new simple type is conceptually defined as

```

```

type E
  EnumType value; // Accessed without dot-notation
  parameter StringType quantity = "";
  parameter EnumType min=e1, max=en;
  parameter EnumType start = e1; // Initial value
  parameter BooleanType fixed = true, // default for parameter/constant;
  = false; // default for other variables
  parameter BooleanType enable = true; // defined for every class
  constant EnumType e1=...;
  ...
  constant EnumType en=...;
equation
  assert(value >= min and value <= max, "Variable value out of limit");
end E;

```

The attributes “start” and “fixed” define the initial conditions for a variable for `analysisType = "static"`. “fixed=false” means an initial guess, i.e., value may be changed by static analyzer. “fixed=true” means a required value. Before other `analysisTypes` (such as “dynamic”) are performed, the `analysisType "static"` has to be carried out first. The resulting consistent set of values for ALL model variables is used as initial values for the analysis to be performed.

The attribute “enable” exists for all classes. This is used for controlling whether outputs of a function are computed or not, see section 3.4.8.2.

The attribute “nominal” gives the nominal value for the variable. The user need not set it even though the standard does not define a default value. *[The nominal value can be used by an analysis tool to determine appropriate tolerances or epsilons, or may be used for scaling. For example, the absolute tolerance for an integrator could be computed as $absTol = abs(nominal) * relTol / 100$. A default value is not provided in order that in cases such as “a=b”, where “b” has a nominal value but not “a”, the nominal value can be propagated to the other variable].* *[For external functions in C89, RealType by default maps to double and IntegerType by default maps to int. In the mapping proposed in Annex F of the C99 standard, RealType/double matches the IEC 60559:1989 (ANSI/IEEE 754-1985) double format. Typically IntegerType represents a 32-bit 2-complement signed integer.]*

3.7 Built-in variable time

All declared variables are functions of the independent variable **time**. Time is a built-in variable available in all

classes, which is treated as an input variable. It is implicitly defined as:

```
input Real time (final quantity = "Time",  
                final unit      = "s");
```

The value of the **start** attribute of time is set to the time instant at which the simulation is started.

[Example:

```
encapsulated model SineSource  
  import Modelica.Math.sin;  
  connector OutPort=output Real;  
  OutPort y=sin(time); // Uses the built-in variable time.  
end SineSource;
```

]

4 Mathematical description of Hybrid DAEs

In this section, the mapping of a Modelica model into an appropriate mathematical description form is discussed.

In a first step, a Modelica translator transforms a hierarchical Modelica model into a "flat" set of Modelica statements, consisting of the equation and algorithm sections of all used components by:

- expanding all class definitions (flattening the inheritance tree) and adding the equations and assignment statements of the expanded classes for every instance of the model
- replacing all connect-statements by the corresponding equations of the connection set (see 3.3.6.1).
- mapping all algorithm sections to equation sets.
- mapping all when clauses to equation sets (see 3.3.4).

As a result of this transformation process, a *set of equations* is obtained consisting of *differential*, *algebraic* and *discrete equations* of the following form ($\mathbf{v} := [\dot{\mathbf{x}}; \mathbf{x}; \mathbf{y}; t; \mathbf{m}; \mathbf{pre}(\mathbf{m}); \mathbf{p}]$):

$$(1a) \quad \mathbf{c} := \mathbf{f}_c(\mathit{relation}(\mathbf{v}))$$

$$(1b) \quad \mathbf{m} := \mathbf{f}_m(\mathbf{v}, \mathbf{c})$$

$$(1c) \quad \mathbf{0} = \mathbf{f}_x(\mathbf{v}, \mathbf{c})$$

where

- p** Modelica variables declared as *parameter* or *constant*, i.e., variables without any time-dependency.
- t** Modelica variable *time*, the independent (real) variable.
- x(t)** Modelica variables of type *Real*, appearing differentiated.
- m(t_e)** Modelica variables of type *discrete Real*, *Boolean*, *Integer* which are unknown. These variables change their value only at event instants t_e. **pre(m)** are the values of **m** immediately before the current event occurred.
- y(t)** Modelica variables of type *Real* which do not fall into any other category (= algebraic variables).
- c(t_e)** The conditions of all **if**-expressions generated including **when**-clauses after conversion, see 3.3.4).
- relation(v)** A relation containing variables v_i, e.g. v₁ > v₂, v₃ >= 0.

For simplicity, the special cases of the **noEvent()** operator and of the **reinit()** operator are not contained in the equations above and are not discussed below.

The generated set of equations is used for simulation and other analysis activities. Simulation means that an initial value problem is solved, i.e., initial values have to be provided for the states \mathbf{x} , section 3.3.7. The equations define a DAE (Differential Algebraic Equations) which may have discontinuities, a variable structure and/or which are controlled by a discrete-event system. Such types of systems are called *hybrid DAEs*. Simulation is performed in the following way:

1. The DAE (1c) is solved by a numerical integration method. In this phase the conditions \mathbf{c} of the if- and when-clauses, as well as the discrete variables \mathbf{m} are kept constant. Therefore, (1c) is a continuous function of continuous variables and the most basic requirement of numerical integrators is fulfilled.
2. During integration, all relations from (1a) are monitored. If one of the relations changes its value an event is triggered, i.e., the exact time instant of the change is determined and the integration is halted. As discussed in section 3.5, relations which depend only on time are usually treated in a special way, because this allows to determine the time instant of the next event in advance.
3. At an event instant, (1) is a mixed set of algebraic equations which is solved for the Real, Boolean and Integer unknowns.
4. After an event is processed, the integration is restarted with 1.

Note, that both the values of the conditions \mathbf{c} as well as the values of \mathbf{m} (all *discrete Real, Boolean and Integer* variables) are only changed at an event instant and that these variables remain constant during continuous integration. At every event instant, new values of the discrete variables \mathbf{m} and of new initial values for the states \mathbf{x} are determined. The change of discrete variables may characterize a new structure of a DAE where elements of the state vector \mathbf{x} are *disabled*. In other words, the number of state variables, algebraic variables and residue equations of a DAE may change at event instants by disabling the appropriate part of the DAE. For clarity of the equations, this is not explicitly shown by an additional index in (1).

At an event instant, including the initial event, the model equations are reinitialized according to the following iteration procedure:

```

known variables:  $\mathbf{x}$ ,  $\mathbf{t}$ ,  $\mathbf{p}$ 
unkown variables:  $d\mathbf{x}/dt$ ,  $\mathbf{y}$ ,  $\mathbf{m}$ ,  $\mathbf{pre}(\mathbf{m})$ ,  $\mathbf{c}$ 

//  $\mathbf{pre}(\mathbf{m})$  = value of  $\mathbf{m}$  before event occurred
loop
  solve (1) for the unknowns, with  $\mathbf{pre}(\mathbf{m})$  fixed
  if  $\mathbf{m} == \mathbf{pre}(\mathbf{m})$  then break
   $\mathbf{pre}(\mathbf{m}) := \mathbf{m}$ 
end loop

```

Solving (1) for the unknowns is non-trivial, because this set of equations contains not only Real, but also Boolean and Integer unknowns. Usually, in a first step these equations are sorted and in many cases the Boolean and Integer unknowns can be just computed by a forward evaluation sequence. In some cases, there remain systems of equations (e.g. for ideal diodes, Coulomb friction elements) and specialized algorithms have to be used to solve them.

Due to the construction of the equations by "flattening" a Modelica model, the hybrid DAE (1) contains a huge number of sparse equations. Therefore, direct simulation of (1) requires sparse matrix methods. However, solving this initial set of equations directly with a numerical method is both unreliable and inefficient. One reason is that many Modelica models, like the mechanical ones, have a DAE index of 2 or 3, i.e., the overall number of states of the model is less than the sum of the states of the sub-components. In such a case, every direct numerical method has the difficulty that the numerical condition becomes worse, if the integrator step size is reduced and that a step size of zero leads to a singularity. Another problem is the handling of idealized

elements, such as ideal diodes or Coulomb friction. These elements lead to *mixed* systems of equations having both *Real* and *Boolean unknowns*. Specialized algorithms are needed to solve such systems.

To summarize, symbolic transformation techniques are needed to transform (1) in a set of equations which can be numerically solved reliably. Most important, the algorithm of Pantelides should to be applied to differentiate certain parts of the equations in order to reduce the index. Note, that also *explicit integration* methods, such as Runge-Kutta algorithms, can be used to solve (1c), after the index of (1c) has been reduced by the Pantelides algorithm: During continuous integration, the integrator provides \mathbf{x} and t . Then, (1c) is a linear or nonlinear system of equations to compute the algebraic variables \mathbf{y} and the state derivatives $d\mathbf{x}/dt$ and the model returns $d\mathbf{x}/dt$ to the integrator by solving these systems of equations. Often, (1c) is just a linear system of equations in these unknowns, so that the solution is straightforward. This procedure is especially useful for *real-time* simulation where usually explicit one-step methods are used.

5 Unit expressions

Unless otherwise stated, the syntax and semantics of unit expressions in Modelica are conform with the international standards ISO 31/0-1992 "General principles concerning quantities, units and symbols" and ISO 1000-1992 "SI units and recommendations for the use of their multiples and of certain other units". Unfortunately, neither these two standards nor other existing or emerging ISO standards define a formal syntax for unit expressions. There are recommendations and Modelica exploits them.

Examples for the syntax of unit expressions used in Modelica: "N.m", "kg.m/s²", "kg.m.s⁻² "1/rad", "mm/s".

5.1 The Syntax of unit expressions

```
unit_expression:
  unit_numerator [ "/" unit_denominator ]

unit_numerator:
  "1" | unit_factors | "(" unit_expression ")"
```

```
unit_denominator:
  unit_factor | "(" unit_expression ")"
```

The unit of measure of a dimension free quantity is denoted by "1". The ISO standard does not define any precedence between multiplications and divisions. The ISO recommendation is to have at most one division, where the expression to the right of "/" either contains no multiplications or is enclosed within parentheses. It is also possible to use negative exponents, for example, "J/(kg.K)" may be written as "J.kg-1.K-1".

```
unit_factors:
  unit_factor [ unit_mulop unit_factors ]
```

```
unit_mulop:
  "."
```

The ISO standard allows that a multiplication operator symbol is left out. However, Modelica enforces the ISO recommendation that each multiplication operator is explicitly written out in formal specifications. For example, Modelica does not support "Nm" for newtonmeter, but requires it to written as "N.m".

The preferred ISO symbol for the multiplication operator is a "dot" a bit above the base line: "⋅". Modelica supports the ISO alternative ".", which is an ordinary "dot" on the base line.

```
unit_factor:
  unit_operand [ unit_exponent ]
```

```
unit_exponent:
  [ "+" | "-" ] integer
```

The ISO standard does not define any operator symbol for exponentiation. A `unit_factor` consists of a `unit_operand` possibly suffixed by a possibly signed integer number, which is interpreted as an exponent. There must be no spacing between the `unit_operand` and a possible `unit_exponent`.

```
unit_operand:
  unit_symbol | unit_prefix unit_symbol
```

```
unit_prefix:
  Y | Z | E | P | T | G | M | k | h | da | d | c | m | u | p | f | a | z |
  y
```

A `unit_symbol` is a string of letters. A basic support of units in Modelica should know the basic and derived units of the SI system. It is possible to support user defined unit symbols. In the base version Greek letters is not supported, but full names must then be written, for example "Ohm".

A `unit_operand` should first be interpreted as a `unit_symbol` and only if not successful the second alternative assuming a prefixed operand should be exploited. There must be no spacing between the `unit_symbol` and a possible `unit_prefix`. The value of the prefixes are according to the ISO standard. The letter "u" is used as a symbol for the prefix micro.

5.2 Examples

- The unit expression "m" means meter and not milli (10^{-3}), since prefixes cannot be used in isolation. For millimeter use "mm" and for squaremeter, m^2 , write "m2".
- The expression "mm2" means $mm^2 = (10^{-3}m)^2 = 10^{-6}m^2$. Note that exponentiation includes the prefix.

The unit expression "T" means Tesla, but note that the letter "T" is also the symbol for the prefix tera which has a multiplier value of 10^{12} .

6 External function interface

6.1 Overview

Here, the word function is used to refer to an arbitrary external routine, whether or not the routine has a return value or returns its result via output parameters (or both). The Modelica external function call interface provides the following:

- Support for external functions written in C and FORTRAN 77. Other languages, e.g. C++ and Fortran 90, may be supported in the future.
- Mapping of argument types from Modelica to the target language and back.
- Natural type conversion rules in the sense that there is a mapping from Modelica to standard libraries of the target language.
- Handling arbitrary parameter order for the external function.
- Passing arrays to and from external functions where the dimension sizes are passed as explicit integer parameters.
- Handling of external function parameters which are used both for input and output.

The format of an external function declaration is as follows.

```

function IDENT string_comment
  { component_clause ";" }
  [ protected { component_clause ";" } ]
  external [ language_specification ] [ external_function_call ] ";"
  [ annotation ";" ]
end IDENT;
```

Components in the public part of an external function declaration shall be declared either as **input** or **output**. *[This is just as for any other function. The components in the protected part allows local variables for temporary storage to be declared.]*

The *language-specification* must currently be one of "C" or "FORTRAN 77". Unless the external language is specified, it is assumed to be C.

The *external-function-call* specification allows functions whose prototypes do not match the default assumptions as defined below to be called. It also gives the name used to call the external function. If the external call is not given explicitly, this name is assumed to be the same as the Modelica name.

The only permissible kinds of expressions in the argument list are identifiers, scalar constants, and the function *size* applied to an array and a constant dimension number. The annotations are used to pass additional information to the compiler when necessary. Currently, the only supported annotation is `arrayLayout`, which can be either "rowMajor" or "columnMajor".

6.2 Argument type mapping

The arguments of the external function are declared in the same order as in the Modelica declaration, unless specified otherwise in an explicit external function call. Protected variables (i.e. temporaries) are passed in the same way as outputs, whereas constants and size-expression are passed as inputs.

6.2.1 Simple types

Arguments of **simple** types are by default mapped as follows for C:

Modelica	C	
	Input	Output
Real	double	double *
Integer	int	int *
Boolean	int	int *
String	const char *	const char **
Enumeration type	int	int *

An exception is made when the argument is of the form `size(..., ...)`. In this case the corresponding C-type is `size_t`.

Strings are NUL-terminated (i.e., terminated by '\0') to facilitate calling of C functions. When returning a non-literal string, the memory for this string can be allocated with function "ModelicaAllocateString" (see section 6.6) *[It is not suitable to use malloc, because a Modelica simulation environment may have its own allocation scheme, e.g., a special stack for local variables of a function]*. After return of the external function, the Modelica environment is responsible for the memory allocated with ModelicaAllocateString (e.g., to free this memory, when appropriate). It is not allowed to access memory that was allocated with ModelicaAllocateString in a previous call of this external function.

Arguments of **simple** types are by default mapped as follows for FORTRAN 77:

Modelica	FORTRAN 77	
	Input	Output
Real	DOUBLE PRECISION	DOUBLE PRECISION
Integer	INTEGER	INTEGER
Boolean	LOGICAL	LOGICAL
Enumeration type	INTEGER	INTEGER

Passing strings to FORTRAN 77 subroutines/functions is currently not supported.

Enumeration types used as arguments are mapped to type `int` when calling an external C function, and to type `INTEGER` when calling an external FORTRAN function. The *i*:th enumeration literal is mapped to integer value *i*, starting at one.

Return values are mapped to enumeration types analogously: integer value 1 is mapped to the first enumeration literal, 2 to the second, etc. Returning a value which does not map to an existing enumeration literal for the

specified enumeration type is an error.

6.2.2 Arrays

Unless an explicit function call is present in the external declaration, an array is passed by its address followed by n arguments of type `size_t` with the corresponding array dimension sizes, where n is the number of dimensions. *[The type `size_t` is a C unsigned integer type.]*

Arrays are by default stored in row-major order when calling C functions and in column-major order when calling FORTRAN 77 functions. These defaults can be overridden by the array layout annotation. See the example below.

The table below shows the mapping of an array argument in the absence of an explicit external function call when calling a C function. The type T is allowed to be any of the simple types which can be passed to C as defined in section 6.2.1 or a record type as defined in section 6.2.3 and it is mapped to the type T' as defined in these sections.

Modelica	C
	Input and Output
$T[dim_1]$	$T' *$, <code>size_t dim₁</code>
$T[dim_1, dim_2]$	$T' *$, <code>size_t dim₁</code> , <code>size_t dim₂</code>
$T[dim_1, \dots, dim_n]$	$T' *$, <code>size_t dim₁</code> , ..., <code>size_t dim_n</code>

The method used to pass array arguments to FORTRAN 77 functions in the absence of an explicit external function call is similar to the one defined above for C: first the address of the array, then the dimension sizes as integers. See the table below. The type T is allowed to be any of the simple types which can be passed to FORTRAN 77 as defined in section 6.2.1 and it is mapped to the type T' as defined in that section.

Modelica	FORTRAN 77
	Input and Output
$T[dim_1]$	T' , <code>INTEGER dim₁</code>
$T[dim_1, dim_2]$	T' , <code>INTEGER dim₁</code> , <code>INTEGER dim₂</code>
$T[dim_1, \dots, dim_n]$	T' , <code>INTEGER dim₁</code> , ..., <code>INTEGER dim_n</code>

[The following two examples illustrate the default mapping of array arguments to external C and FORTRAN 77 functions.]

```

function foo
  input   Real    a[:, :, :];
  output Real    x;
  external;
end foo;

```

The corresponding C prototype is as follows:

```
double foo(double *, size_t, size_t, size_t);
```

If the external function is written in FORTRAN 77, i.e.:

```

function foo
  input   Real    a[:, :, :];
  output  Real    x;
  external "FORTRAN 77";
end foo;

```

the default assumptions correspond to a FORTRAN 77 function defined as follows:

```

FUNCTION foo(a, d1, d2, d3)
  DOUBLE PRECISION(d1,d2,d3) a
  INTEGER           d1
  INTEGER           d2
  INTEGER           d3
  DOUBLE PRECISION           foo
  ...
END

```

]

When an explicit call to the external function is present, the array and the sizes of its dimensions must be passed explicitly.

[This example shows how to arrays can be passed explicitly to an external FORTRAN 77 function when the default assumptions are unsuitable.

```

function foo
  input   Real    x[:];
  input   Real    y[size(x,1), :];
  input   Integer  i;
  output  Real    u1[size(y,1)];
  output  Integer u2[size(y,2)];
  external "FORTRAN 77" myfoo(x, y, size(x,1), size(y,2),
                             u1, i, u2);
end foo;

```

The corresponding FORTRAN 77 subroutine would be declared as follows:

```

SUBROUTINE myfoo(x, y, n, m, u1, i, u2)
  DOUBLE PRECISION(n)    x
  DOUBLE PRECISION(n,m)  y
  INTEGER                n
  INTEGER                m
  DOUBLE PRECISION(n)    u1
  INTEGER                i
  DOUBLE PRECISION(m)    u2
  ...
END

```

This example shows how to pass an array in column major order to a C function.

```

function fie
  input  Real[:, :] a;
  output Real b;
  external;
  annotation(arrayLayout = "columnMajor");
end fie;

```

This corresponds to the following C-prototype:

```
double fie(double *, size_t, size_t);
]
```

6.2.3 Records

Mapping of record types is only supported for C. A Modelica record class that contains simple types, other record elements, or arrays with fixed dimensions thereof, is mapped as follows:

- The record class is represented by a struct in C.
- Each element of the Modelica record is mapped to its corresponding C representation. The elements of the Modelica record class are declared in the same order in the C struct.
- Arrays are mapped to the corresponding C array, taking the default array layout or any explicit `arrayLayout-directive` into consideration.
- Records are passed by reference (i.e. a pointer to the record is being passed).

For example,

```

record R                                struct R {
  Real x;                                  double x;
  Integer y[10];                          int y[10];
  Real z;                                  double z;
end R;                                    };

```

is mapped to

6.3 Return type mapping

If there is a single output parameter and no explicit call of the external function, or if there is an explicit external call in the form of an equation, in which case the LHS must be one of the output parameters, the external routine is assumed to be a value-returning function. Mapping of the return type of functions is performed as indicated in the table below. Storage for arrays as return values is allocated by the calling routine, so the dimensions of the returned array are fixed at call time. Otherwise the external function is assumed not to return anything; i.e., it is really a procedure or, in C, a `void`-function. *[In this case, argument type mapping according to section 6.2 is performed in the absence of any explicit external function call.]*

Return types are by default mapped as follows for C and FORTRAN 77:

Modelica	C	FORTRAN 77
Real	double	DOUBLE PRECISION
Integer	int	INTEGER
Boolean	int	LOGICAL
String	const char*	Not allowed.
$T[dim_1, \dots, dim_n]$	$T' *$	T'
Enumeration type	int	INTEGER
Record	See section 6.2.3.	Not allowed.

The element type T of an array can be any simple type as defined in section 6.2.1 or, for C, a record type as defined in section 6.2.3. The element type T is mapped to the type T' as defined in these sections.

6.4 Aliasing

Any potential aliasing in the external function is the responsibility of the tool and not the user. An external function is not allowed to internally change the inputs (even if they are restored before the end of the function).

[Example:

```
function foo
  input Real x;
  input Real y;
  output Real z:=x;
  external "FORTRAN 77" myfoo(x,y,z);
end foo;
```

The following Modelica function:

```
function f
  input Real a;
  output Real b;
algorithm
  b:=foo(a,a);
  b:=foo(b,2*b);
end f;
```

can on most systems be transformed into the following C function

```
double f(double a) {
  extern void myfoo_(double*,double*,double*);
  double b,temp1,temp2;
  myfoo_(&a,&a,&b);
  temp1=2*b;
  temp2=b;
  myfoo_(&b,&temp1,&temp2);
  return temp2;
}
```

The reason for not allowing the external function to change the inputs is to ensure that inputs can be stored in static memory and to avoid superfluous copying (especially of matrices). If the routine does not satisfy the requirements the interface must copy the input argument to a temporary. This is rare but occurs e.g. in *dormlq* in some Lapack implementations. In those special cases the writer of the external interface have to copy the input to a temporary. If the first input was changed internally in *myfoo* the designer of the interface would have to change the interface function "foo" to:

```
function foo
  input Real x;
  protected Real xtemp:=x; // Temporary used because myfoo changes its input
  public input Real y;
  output Real z;
  external "FORTRAN 77" myfoo(xtemp,y,z);
end foo;
```

Note that we discuss input arguments for Fortran-routines even though Fortran 77 does not formally have input arguments and forbid aliasing between any pair of arguments to a function (section 15.9.3.6 of X3J3/90.4). For the few (if any) Fortran 77 compilers that strictly follow the standard and are unable to handle aliasing between input variables the tool must transform the first call of *foo* into

```
temp1=a; /* Temporary to avoid aliasing */
```

```
myfoo_(&a, &temp1, &b);
```

The use of the function foo in Modelica is uninfluenced by these considerations.]

6.5 Examples

6.5.1 Input parameters, function value

[Here all parameters to the external function are input parameters. One function value is returned. If the external language is not specified, the default is "C", as below.]

```
function foo
  input Real    x;
  input Integer y;
  output Real   w;
  external;
end foo;
```

This corresponds to the following C-prototype:

```
double foo(double, int);
```

Example call in Modelica:

```
z = foo(2.4, 3);
```

Translated call in C:

```
z = foo(2.4, 3);
```

6.5.2 Arbitrary placement of output parameters, no external function value

In the following example, the external function call is given explicitly which allows passing the arguments in a different order than in the Modelica version.

```
function foo
  input Real    x;
  input Integer y;
  output Real   u1;
  output Integer u2;
  external "C" myfoo(x, u1, y, u2);
end foo;
```

This corresponds to the following C-prototype:

```
void myfoo(double, double *, int, int *);
```

Example call in Modelica:

```
(z1, i2) = foo(2.4, 3);
```

Translated call in C:

```
myfoo(2.4, &z1, 3, &i2);
```

6.5.3 External function with both function value and output variable

The following external function returns two results: one function value and one output parameter value. Both are mapped to Modelica output parameters.

```
function foo
  input Real    x;
  input Integer y;
```

```

output Real      funcvalue;
output Integer  out1;
external "C" funcvalue = myfoo(x, y, out1);
end foo;

```

This corresponds to the following C-prototype:

```
double myfoo(double, int, int *);
```

Example call in Modelica:

```
(z1,i2) = foo(2.4, 3);
```

Translated call in C:

```
z1 = myfoo(2.4, 3, &i2);
```

]

6.6 Utility functions

The following utility functions can be called in external Modelica functions written in C. These functions are defined in file **ModelicaUtilities.h**:

ModelicaMessage	<i>void ModelicaMessage(const char* string)</i> Output the message string (no format control).
ModelicaFormatMessage	<i>void ModelicaFormatMessage(const char* string, ...)</i> Output the message under the same format control as the C-function printf.
ModelicaError	<i>void ModelicaError(const char* string)</i> Output the error message string (no format control). This function never returns to the calling function, but handles the error similarly to an assert in the Modelica code.
ModelicaFormatError	<i>void ModelicaFormatError(const char* string, ...)</i> Output the error message under the same format control as the C-function printf. This function never returns to the calling function, but handles the error similarly to an assert in the Modelica code.
ModelicaAllocateString	<i>char* ModelicaAllocateString(size_t len)</i> Allocate memory for a Modelica string which is used as return argument of an external Modelica function. Note, that the storage for string arrays (= pointer to string array) is still provided by the calling program, as for any other array. If an error occurs, this function does not return, but calls "ModelicaError".
ModelicaAllocateStringWithErrorReturn	<i>char* ModelicaAllocateStringWithErrorReturn(size_t len)</i> Same as ModelicaAllocateString, except that in case of error, the function returns 0. This allows the external function to close files and free other open resources in case of error. After cleaning up resources use ModelicaError or ModelicaFormatError to signal the error.

6.7 External objects

External functions may have internal memory reported between function calls. Within Modelica this memory is defined as instance of the predefined class **ExternalObject** according to the following rules:

- There is a predefined **partial** class "ExternalObject"
[since the class is partial, it is not possible to define an instance of this class].
- An external object class shall be directly extended from "ExternalObject", shall have exactly two function definitions, called "constructor" and "destructor", and shall not contain other elements.
- The constructor function is called exactly once before the first use of the object. For each completely constructed object, the destructor is called exactly once, after the last use of the object, even if an error occurs. The constructor shall have exactly one output argument in which the constructed ExternalObject is returned. The destructor shall have no output arguments and the only input argument of the destructor shall be the ExternalObject. It is not legal to call explicitly the constructor and destructor functions.
- Classes derived from ExternalObject can neither be used in an extends clause nor in a short class definition.
- External functions may be defined which operate on the internal memory of an ExternalObject. An ExternalObject used as input argument or return value of an external C-function is mapped to the C-type "void*".

[Example:

*A user-defined table may be defined in the following way as an ExternalObject
(the table is read in a user-defined format from file and has memory for the last used table interval):*

```

class MyTable
  extends ExternalObject;
  function constructor
    input String fileName = "";
    input String tableName = "";
    output MyTable table;
    external "C" table = initMyTable(fileName, tableName);
  end constructor;

  function destructor "Release storage of table"
    input MyTable table;
    external "C" closeMyTable(table);
  end destructor;
end MyTable;

```

and used in the following way:

```

model test "Define a new table and interpolate in it"
  MyTable table=MyTable(fileName="testTables.txt",
                        tableName="table1"); // call initMyTable

  Real y;
  equation
    y = interpolateMyTable(table, time);
  end test;

```

This requires to provide the following Modelica function:

```

function interpolateMyTable "Interpolate in table"
  input MyTable table;
  input Real u;
  output Real y;
  external "C" y = interpolateMyTable(table, u);
end interpolateTable;

```

The external C-functions may be defined in the following way:

```

typedef struct { /* User-defined datastructure of the table */
  double* array; /* nrow*ncolumn vector */
  int nrow; /* number of rows */
  int ncol; /* number of columns */
  int type; /* interpolation type */
  int lastIndex; /* last row index for search */
} MyTable;

void* initMyTable(char* fileName, char* tableName) {
  MyTable* table = malloc(sizeof(MyTable));
  if ( table == NULL ) ModelicaError("Not enough memory");
  // read table from file and store all data in *table
  return (void*) table;
};

void closeMyTable(void* object) { /* Release table storage */
  MyTable* table = (MyTable*) object;
  if ( object == NULL ) return;
  free(table->array);
  free(table);
}

double interpolateMyTable(void* object, double u) {
  MyTable* table = (MyTable*) object;
  double y;
  // Interpolate using "table" data (compute y)
  return y;
};
]

```

7 Annotations for graphical objects

A graphical representation of a class consists of two abstraction layers, icon layer and diagram layer showing graphical objects, component icons, connectors and connection lines. The icon representation typically visualizes the component by hiding hierarchical details. The hierarchical decomposition is typically described in the diagram layer showing icons of subcomponents.

Note that a Modelica tool is free to define and use other attributes, in addition to those defined here. The only requirement is that any tool must be able to save files with all attributes intact, including those that are not used. To ensure this, annotations must be represented with constructs according to the Modelica grammar. The specification in this document is used to convey semantic meaning for a subset that shall be supported by all tools.

Graphical annotations described in this chapter ties into the Modelica grammar as follows.

```
graphical_annotations :
  annotation "(" [ layer_annotations ] ")"

layer_annotations:
  ( documentation | icon_layer | info_layer ) ["," layer_annotations ]

documentation :
  Documentation "(" "info" "=" STRING ")"
```

Tools must support at least one documentation string as annotation. How the tool interprets this information is unspecified. *[The tags `<HTML>` and `</HTML>` have been defined to optionally begin and end the string to indicate to the tool that the string content is HTML encoded.]*

Layer descriptions (start of syntactic description):

```
icon_layer :
  "Icon" "(" [ coordsys_specification "," ] graphics ")"

diagram_layer :
  "Diagram" "(" [ coordsys_specification "," ] graphics ")"
```

[Example:

```
annotation (
  Icon(coordinateSystem={{-10,-10}, {10,10}},
    graphics={Rectangle(extent={{-10,-10}, {10,10}}),
      Text({{-10,-10}, {10,10}}, textString="Icon")}));
]
```

The graphics is specified as an ordered sequence of graphical primitives, which are described below. *[Note that the ordered sequence is syntactically a valid Modelica annotation, although there is no mechanism for defining an array of heterogeneous objects in Modelica.]*

7.1 Common definitions

The following common definitions are used to define graphical annotations in the later sections.

```
type DrawingUnit = Real(final unit="mm");
type Point       = DrawingUnit[2]   "{x, y}";
type Extent      = Point[2]
                  "Defines a rectangular area {{x1, y1}, {x2, y2}}";
```

The interpretation of "unit" is with respect to printer output in natural size (not zoomed). *[On the screen, 1 mm in "natural size" is typically mapped to 4 pixels.]*

All graphical entities have an visible attribute which indicates if the entity should be shown.

```
partial record GraphicItem
  Boolean visible = true;
end GraphicItem;
```

7.1.1 Coordinate systems

Each of the layers have their own coordinate system. A coordinate system is defined by the coordinates of two points, at the lower left corner and at the upper right corner.

```
record CoordinateSystem   "Attribute to layer"
  Extent extent;
end CoordinateSystem;
```

[A coordinate system for an icon could for example be defined as:

```
CoordinateSystem(extent = {{-10, -10}, {10, 10}});
```

i.e. a first quadrant coordinate system with width 20 units and height 20 units. The exact interpretation of the units is to a certain extent tool dependent.]

The coordinate systems for icon and diagram are by default defined as follows; the array of GraphicItem represents an ordered list of graphical primitives.

```
record Icon               "Representation of Icon layer"
  CoordinateSystem coordinateSystem(extent =
    {{-10, -10}, {10, 10}});
  GraphicItem[:] graphics;
end Icon;

record Diagram           "Representation of Diagram layer"
```

```

CoordinateSystem coordinateSystem(extent =
  {{-100, -100}, {100, 100}});
GraphicItem[:] graphics;
end Diagram;

```

[A coordinate system for a connector icon could for example be defined as:

```

CoordinateSystem(extent = {{-1, -1}, {1, 1}});
]

```

7.1.2 Graphical properties

Properties of graphical objects and connection lines are described using the following attribute types.

```

type Color = Integer[3] (min=0, max=255)    "RGB representation";
constant Color DefaultColor = zeros(3);    // Black
type LinePattern = enumeration(None, Solid, Dash, Dot, DashDot,
  DashDotDot);
type FillPattern = enumeration(None, Solid, Horizontal, Vertical,
  Cross, Forward, Backward, CrossDiag, HorizontalCylinder,
  VerticalCylinder, Sphere);
type BorderPattern = enumeration(None, Raised, Sunken, Engraved);

```

The FillPattern attributes Horizontal, Vertical, Cross, Forward, Backward and CrossDiag specify fill patterns drawn with the border color over the fillColor.

The attributes HorizontalCylinder, VerticalCylinder and Sphere specify gradients that represent a horizontal cylinder, a vertical cylinder and a sphere, respectively.

The border pattern attributes Raised and Sunken represent panels which are rendered in a system-dependent way. The border pattern Engraved represents a system-dependent outline.

```

type Arrow = enumeration(None, Open, Filled, Half);
type TextStyle = enumeration(Bold, Italic, UnderLine);

```

Filled shapes have the following attributes for the border and interior.

```

record FilledShape    "Style attributes for filled shapes"
  Color lineColor = Black    "Color of border line";
  Color fillColor = Black    "Interior fill color";

  LinePattern pattern = LinePattern.Solid    "Border line pattern";
  FillPattern fillPattern = FillPattern.None

```

```
"Interior fill pattern";
```

```
DrawingUnit lineThickness = 0.25 "Border line thickness"
end Style;
```

When color gradient is specified, the color fades from the specified fill color to white and black using the hue and saturation of the specified color.

7.2 Component instance and extends clause

A component instance and an extends clause can be placed within a diagram or icon layer. It has an annotation with a Placement modifier to describe the placement. Placements are defined in term of coordinate systems transformations:

```
record Transformation
  DrawingUnit x=0, y=0;
  Real scale=1, aspectRatio=1;
  Boolean flipHorizontal=false, flipVertical=false;
  Real rotation(quantity="angle", unit="deg")=0;
end Transformation;
```

The coordinates {x,y} define the position of the origin of the component's icon coordinate system. The scale attribute defines a uniform scale factor of the icon's coordinate system when draw in the coordinate system of the enclosing class. The aspectRatio attribute defines non-uniform scaling, where $sy=aspectRatio*sx$. The flipHorizontal and flipVertical attributes define horizontal and vertical flipping around the coordinate system axes. The graphical operations are applied in the order: scaling, flipping and rotation.

```
record Placement          "Attribute for component and extends"
  extends GraphicItem;
  Transformation transformation;
  Transformation iconTransformation "Placement in icon layer";
end Placement;
```

A connector can be shown in both an icon layer and a diagram layer of a class. Since the coordinate systems typically are different, placement information needs to be given using two different coordinate systems. More flexibility than just using scaling and translation is needed since the abstraction views might need different visual placement of the connectors. *Placement* gives the placement in the diagram layer and *iconPlacement* gives the placement in an icon layer. When a connector is shown in a diagram layer, it's diagram layer is shown to facilitate opening up a hierarchical connector to allow connections to it's internal subconnectors.

For connectors, the icon layer is used to represent a connector when it is shown in the icon layer of the enclosing model. The diagram layer of the connector is used to represent it when shown in the diagram layer of the enclosing model. Protected connectors are only shown in the diagram layer. Public connectors are shown in both the diagram layer and the icon layer. Non-connector components are only shown in the diagram layer.

7.3 Connections

A connection is specified with an annotation containing a Line primitive, as specified below. *[Example:*

```
connect (a.x, b.x)
  annotation (Line(points={{-25,30}, {10,30}, {10,-20}, {40,-20}}));
```

];

7.4 Graphical primitives

This section describes the graphical primitives that can be used to define the graphical objects in an annotation.

7.4.1 Line

A line is specified as follows:

```
record Line
  extends GraphicItem;

  Point points[:];

  Color color = Black;
  LinePattern pattern = LinePattern.Solid;
  DrawingUnit thickness = 0.25;

  Arrow arrow[2] = {Arrow.None, Arrow.None};   "{start arrow, end arrow}"
  DrawingUnit arrowSize=3;
  Boolean smooth = false                       "Spline";
end Line;
```

Note that the `Line` primitive is also used to specify the graphical representation of a connection.

7.4.2 Polygon

A polygon is specified as follows:

```
record Polygon
  extends GraphicItem;
  extends FilledShape;

  Point points[:];
  Boolean smooth = false                       "Spline outline";
end Polygon;
```

The polygon is automatically closed, if the first and the last points are not identical.

7.4.3 Rectangle

A rectangle is specified as follows:

```
record Rectangle
  extends GraphicItem;
  extends FilledShape;
  BorderPattern borderPattern;
  Extent extent;
```

```

    DrawingUnit radius           "Corner radius";
end Rectangle;

```

The extent specifies the bounding box of the rectangle. If radius is specified, the rectangle is drawn with rounded corners of the given radius.

7.4.4 Ellipse

An ellipse is specified as follows:

```

record Ellipse
  extends GraphicItem;
  extends FilledShape;
  Extent extent;
end Ellipse;

```

The extent specifies the bounding box of the ellipse.

7.4.5 Text

A text string is specified as follows:

```

record Text
  extends GraphicItem;
  extends FilledShape;
  Extent extent;
  String textString;
  DrawingUnit fontSize;
  String fontName;
  TextStyle textStyle[:];
end Text;

```

The style attribute `fontSize` specifies the font size. If the `fontSize` attribute is 0 the text is scaled to fit its extent. Otherwise, the size specifies the absolute size. *[Note: the unit "point" is 1/72 inch, approximately 0.35 mm.]*

The style attribute `textStyle` specifies variations of the font.

7.4.6 Bitmap

A bitmap image is specified as follows:

```

record BitMap
  extends GraphicItem;
  Extent extent;
  String fileName           "Name of bitmap file";
  String imageSource       "Pixmap representation of bitmap";
end BitMap;

```

The bitmap primitive renders a graphical bitmap image. The data of the image can either be stored on an external

file or in the annotation itself. The image is scaled to fit the extent.

When the attribute `fileName` is specified, the string refers to an external file containing image data. The mapping from the string to the file is unspecified. The supported file formats include PNG, BMP and JPEG, other supported file formats are unspecified.

When the attribute `imageSource` is specified, the string contains the image data. The image is representation the Pixmap format. *[Note: the Pixmap format is well defined and can be used both as a file format and embedded as a string. There are public-domain libraries for reading and writing Pixmap files.]*

The image is uniformly scaled [to preserve aspect ratio] so it exactly fits within the extent [touching the extent along one axis]. The center of the image is positioned at the center of the extent.

8 Modelica standard library

The pre-defined, free "**package** Modelica" is shipped together with a Modelica translator. It is an extensive standard library of pre-defined components in several domains. Furthermore, it contains a standard set of **type** and **interface** definitions in order to influence the trivial decisions of model design process. If, as far as possible, standard quantity types and connectors are relied on in modeling work, model compatibility and thereby reuse is enhanced. Achieving model compatibility, without having to resort to explicit coordination of modeling activities, is essential to the formation of globally accessible libraries. Naturally, a modeller is not required to use the standard library and may add any number of local base definitions.

The library will be amended and revised as part of the ordinary language revision process. It is expected that informal standard base classes will develop in various domains and that these gradually will be incorporated into the Modelica standard library.

The type definitions in the library are based on ISO 31-1992. Several ISO quantities have long names that tend to become awkward in practical modeling work. For this reason, shorter alias-names are also provided if necessary. Using, e.g., "ElectricPotential" repeatedly in a model becomes cumbersome and therefore "Voltage" is supplied as an alternative.

The standard library is not limited to pure SI units. Whenever common engineering practice uses a different set of (possibly inconsistent) units, corresponding quantities will be allowed in the standard library, for example English units. It is also frequently common to write models with respect to scaled SI units in order to improve the condition of the model equations or to keep the actual values around one for easier reading and writing of numbers.

The connectors and partial models have predefined graphical attributes in order that the basic visual appearance is the same in all Modelica based systems.

The complete Modelica package can be downloaded from <http://www.Modelica.org/library/library.html>. Below, the introductory documentation of this library is given. Note, that the Modelica package is still under development.

package Modelica

annotation(Documentation(info="

/* The Modelica package is a standardized, pre-defined and **free** package, that is shipped together with a Modelica translator. The package provides constants, types, connectors, partial models and model components in various disciplines.

In the Modelica package the following conventions are used:

- Class and instance names are written in upper and lower case letters, e.g., "ElectricCurrent". An underscore is only used at the end of a name to characterize a lower or upper index, e.g., body_low_up.
- Type names start always with an upper case letter.

Instance names start always with a lower case letter with only a few exceptions, such as "T" for a temperature instance.

- A package XXX has its interface definitions in subpackage XXX.Interface, e.g., Electrical.Interface.

- Preferred instance names for connectors:
p,n: positive and negative side of a partial model.
a,b: side "a" and side "b" of a partial model
(= connectors are completely equivalent).

```
*/  
");  
end Modelica;
```

9 Revision history

This section describes the history of the Modelica Language Design, and its contributors. The current version of this document is available from <http://www.modelica.org/>.

9.1 Modelica 2.0

Modelica 2.0 was released January, 30 2002, and the draft was released on December 18 in 2001. The Modelica 2.0 specification was edited by Hans Olsson. Modelica is a *registered trademark* owned by the Modelica Association since November 2001.

9.1.1 Contributors to the Modelica Language, version 2.0

Peter Aronsson, Linköping University, Sweden
Bernhard Bachmann, University of Applied Sciences, Bielefeld
Peter Beater, University of Paderborn, Germany
Dag Brück, Dynasim, Lund, Sweden
Peter Bunus, Linköping University, Sweden
Hilding Elmquist, Dynasim, Lund, Sweden
Vadim Engelson, Linköping University, Sweden
Peter Fritzon, Linköping University, Sweden
Rüdiger Franke, ABB Corporate Research, Ladenburg
Pavel Grozman, Equa, Stockholm, Sweden
Johan Gunnarsson, MathCore, Linköping
Mats Jirstrand, MathCore, Linköping
Sven Erik Mattsson, Dynasim, Lund, Sweden
Hans Olsson, Dynasim, Lund, Sweden
Martin Otter, German Aerospace Center, Oberpfaffenhofen, Germany
Levon Saldamli, Linköping University, Sweden
Michael Tiller, Ford Motor Company, Dearborn, MI, U.S.A.
Hubertus Tummescheit, Lund Institute of Technology, Sweden
Hans-Jürg Wiesmann, ABB Switzerland Ltd., Corporate Research, Baden, Switzerland

9.1.2 Main changes in Modelica 2.0

A detailed description of the enhancements introduced by Modelica 2.0 are given in the papers

- M. Otter, H. Olsson: *New Features in Modelica 2.0*. 2nd International Modelica Conference, March 18-19, DLR Oberpfaffenhofen, Proceedings, pp. 7.1 - 7.12, 2002. This paper can be downloaded from http://www.Modelica.org/Conference2002/papers/p01_Otter.pdf
- Mattsson S. E., Elmquist H., Otter M., and Olsson H.: *Initialization of Hybrid Differential-Algebraic Equations in Modelica 2.0*. 2nd International Modelica Conference, March 18-19, DLR Oberpfaffenhofen, Proceedings, pp. 9 - 15, 2002. This paper can be downloaded from http://www.Modelica.org/Conference2002/papers/p02_Mattsson.pdf

The main changes in Modelica 2.0 are:

- Full specification of initialization in order to compute consistent initial values of all variables appearing in a model before performing an operation, such as simulation or linearization.
- Specified the graphical appearance of Modelica object diagrams, thereby ensuring portability of model topology information and improving the previous informal graphical description, e.g., with separate icon and diagram positions.
- Enumeration types to allow the definition of options and properties in an understandable, safe and efficient way.
- Support for (optional) explicit preference in state-selection in order that a modeler can incorporate application specific knowledge to guide the solution process, e.g., for real-time simulation.
- Iterators in array constructors and reduction operators, to support more powerful expressions, especially in declarations, in order to avoid inconvenient and less efficient local function definitions.
- Support for generic formulation of blocks applicable to both scalar and vector connectors, connection of (automatically) vectorized blocks, and simpler input/output connectors. This allows significant simplifications of the input/output block library of Modelica, e.g., since only scalar versions of all blocks have to be provided. Furthermore, new library components can be incorporated more easily.
- Record constructor to allow, e.g., the construction of data sheet libraries.
- Functions with mixed positional and named arguments. Optional results and default arguments make the same function fit for beginners and expert users.
- Additional utilities for external C-functions that are interfaced to Modelica models, especially supporting external functions returning strings and external functions with internal memory (e.g., to interface user-defined tables, property databases, sparse matrix handling, hardware interfaces).
- Added an index, and specification of some basic constructs that had previously not formally be defined, such as while-clauses, if-clauses.

The language changes are backward compatible, except for the introduction of the new keyword enumeration. The library change of the block library which will become available soon requires changes in user-models.

9.2 Modelica 1.4

Modelica 1.4 was released December 15, 2000. The Modelica Association was formed in Feb. 5, 2000 and is now responsible for the design of the Modelica language. The Modelica 1.4 specification was edited by Hans Olsson and Dag Brück.

9.2.1 Contributors to the Modelica Language, version 1.4

Bernhard Bachmann, Fachhochschule Bielefeld, Germany
 Peter Bunus, MathCore, Linköping, Sweden
 Dag Brück, Dynasim, Lund, Sweden
 Hilding Elmqvist, Dynasim, Lund, Sweden
 Vadim Engelson, Linköping University, Sweden
 Jorge Ferreira, University of Aveiro, Portugal
 Peter Fritzson, Linköping University, Linköping, Sweden
 Pavel Grozman, Equa, Stockholm, Sweden

Johan Gunnarsson, MathCore, Linköping, Sweden
 Mats Jirstrand, MathCore, Linköping, Sweden
 Clemens Klein-Robbenhaar, Germany
 Pontus Lidman, MathCore, Linköping, Sweden
 Sven Erik Mattsson, Dynasim, Lund, Sweden
 Hans Olsson, Dynasim, Lund, Sweden
 Martin Otter, German Aerospace Center, Oberpfaffenhofen, Germany
 Tommy Persson, Linköping University, Sweden
 Levon Saldamli, Linköping University, Sweden
 André Schneider, Fraunhofer Institute for Integrated Circuits, Dresden, Germany
 Michael Tiller, Ford Motor Company, Dearborn, MI, U.S.A.
 Hubertus Tummescheit, Lund Institute of Technology, Sweden
 Hans-Jürg Wiesmann, ABB Corporate Research Ltd., Baden, Switzerland

9.2.2 Contributors to the Modelica Standard Library

Peter Beater, University of Paderborn, Germany
 Christoph Clauß, Fraunhofer Institute for Integrated Circuits, Dresden, Germany
 Martin Otter, German Aerospace Center, Oberpfaffenhofen, Germany
 André Schneider, Fraunhofer Institute for Integrated Circuits, Dresden, Germany
 Hubertus Tummescheit, Lund Institute of Technology, Sweden

9.2.3 Main Changes in Modelica 1.4

- Removed declare-before-use rule. This simplifies graphical user environments, because there exists no order of declarations when components are graphically composed together.
- Refined package concept by introducing encapsulated classes and import mechanism. Encapsulated classes can be seen as "self-contained units": When copying or moving an encapsulated class, at most the import statements in this class have to be changed.
- Refined when-clause: The nondiscrete keyword is removed, equations in when-clauses must have a unique variable name on left hand side variable and the exact mapping of when-clauses to equations is defined. As a result, when-clauses are now precisely defined without referring to a sorting algorithm and it is possible to handle algebraic loops between when-clauses with different conditions and between when-clauses and the continuous-time part of a model. The discrete keyword is now optional, simplifying the library development because only one type of connector is needed and not several types which do contain or do not contain the discrete prefix on variables. Additionally, when-clauses in algorithm sections may have elsewhen clauses which simplifies the definition of priorities between when-clauses.
- For replaceable declarations: allowed constraining clauses, and annotations listing suitable redeclarations. This allows a graphical user environment to automatically build menus with meaningful choices.
- Functions can specify their derivative. This allows, e.g., the application of the Pantelides algorithm to reduce the index of a DAE also for external functions.
- New built-in operator "**rem**" (remainder) and the built-in operators **div**, **mod**, **ceil**, **floor**, **integer**, previously only allowed to be used in when-clauses can now be used everywhere, because state events are automatically generated when the result value of one of these operator changes discontinuously.
- Quantity attribute also for base types Boolean, Integer, String (and not only for Real), in order to allow

abstracted variables to refer to physical quantities (e.g. Boolean `i(quantity="Current")` is true if current is flowing and is false if no current is flowing).

- final keyword also allowed in declaration, to prevent modification. Example

```

model A
  Real x[:];
  final Integer n=size(x,1);
end A;
      
```
- Several minor enhancements, such as usage of dot-notation in modifications (e.g.: "`A x (B.C=1, B.D=2)`" is the same as "`A x (B (C=1, D=2));`") .
- Internally restructured specification.

Modelica 1.4 is backwards compatible with Modelica 1.3, with the exception of (1) some exotic cases where different results are achieved with the removed "declare-before-use-rule" and the previous declaration order, (2) when-clauses in equations sections, which use the general form "`expr1 = expr2`" (now only "`v=expr`" is allowed + some special cases for functions), (3) some exotic cases where a when-clause may be no longer evaluated at the initial time, because the initialization of the when-condition is now defined in a more meaningful way (before Modelica 1.4, every condition in a when-clause has a "previous" value of false), and (4) models containing the nondiscrete keyword which was removed.

9.3 Modelica 1.3 and older versions.

Modelica 1.3 was released December 15, 1999.

9.3.1 Contributors up to Modelica 1.3

The following list contributors and their affiliations at the time when Modelica 1.3 was released.

H. Elmqvist¹,

B. Bachmann², F. Boudaud³, J. Broenink⁴, D. Brück¹, T. Ernst⁵, R. Franke⁶, P. Fritzson⁷, A. Jeandel³, P. Grozman¹², K. Juslin⁸, D. Kågedal⁷, M. Klose⁹, N. Loubere³, S. E. Mattsson¹, P. J. Mosterman¹¹, H. Nilsson⁷, H. Olsson¹, M. Otter¹¹, P. Sahlin¹², A. Schneider¹³, M. Tiller¹⁵, H. Tummescheit¹⁰, H. Vangheluwe¹⁶

¹ Dynasim AB, Lund, Sweden

² ABB Corporate Research Center Heidelberg

³ Gaz de France, Paris, France

⁴ University of Twente, Enschede, Netherlands

⁵ GMD FIRST, Berlin, Germany

⁶ ABB Network Partner Ltd. Baden, Switzerland

⁷ Linköping University, Sweden

⁸ VTT, Espoo, Finland

⁹ Technical University of Berlin, Germany

¹⁰ Lund University, Sweden

¹¹ DLR Oberpfaffenhofen, Germany

¹² Bris Data AB, Stockholm, Sweden

¹⁵ Ford Motor Company, Dearborn, MI, U.S.A.

¹⁶ University of Gent, Belgium

9.3.2 Main changes in Modelica 1.3

Modelica 1.3 was released December 15, 1999.

- Defined connection semantics for inner/outer connectors.
- Defined semantics for protected element.
- Defined that least variable variability prefix wins.
- Improved semantic definition of array expressions.
- Defined scope of for-loop variables.

9.3.3 Main changes in Modelica 1.2

Modelica 1.2 was released June 15, 1999.

- Changed the external function interface to give greater flexibility.
- Introduced inner/outer for dynamic types.
- Redefined final keyword to only restrict further modification.
- Restricted redeclaration to replaceable elements.
- Defined semantics for if-clauses.
- Defined allowed code optimizations.
- Refined the semantics of event-handling.
- Introduced fixed and nominal attributes.
- Introduced terminate and analysisType.

9.3.4 Main Changes in Modelica 1.1

Modelica 1.1 was released in December 1998.

Major changes:

- Specification as a separate document from the rationale.
- Introduced prefixes discrete and nondiscrete.
- Introduced pre and when.
- Defined semantics for array expressions.
- Introduced built-in functions and operators (only connect was present in Modelica 1.0).

9.3.5 Modelica 1.0

Modelica 1, the first version of Modelica, was released in September 1997, and had the language specification as a short appendix to the rationale.
